We developed a two-step PCR-based strategy to detect genes encoding OqxAB, allowing a specific assignment of Tn6010-associated oqxAB in Enterobacteriaceae. Chromosomal location in this setup was confirmed by hybridization with I-CeuI-restricted genomes. This approach led us to find that Klebsiella sp. and Raoultella sp. reference strains chromosomally carried oqxAB.

our plasmid-mediated quinolone resistance (PMQR) mechanisms have been described in *Enterobacteriaceae* so far: Qnr, AAC(6')-Ib-cr, QepA, and OqxAB (1–4). OqxAB belongs to the resistance-nodulation-cell-division (RND) family multidrug efflux pump, and OqxA and OqxB have shown high homology with the AcrAB pump from *Escherichia coli* (4). It has been shown that OqxAB-encoding genes may be located in *Enterobacteriaceae* on the conjugative plasmid pOLA52, within a composite transposon Tn6010 flanked by IS26 (5), but also natively on the chromosome in *Klebsiella pneumoniae* without association to a transposon (6, 7).

As for other PMQR, OqxAB alone confers low-level resistance to fluoroquinolones (8). Although the increased MIC of ciprofloxacin remains below the critical concentration, categorizing the enterobacterial isolate as susceptible, it has been shown that PMQR pose a challenge to antimicrobial treatments (9). Moreover, differentiation between plasmid-borne and chromosomal locations of these genes has a stake in preventing the spread of such resistance markers (10). All together, these data underscore the importance of setting up molecular detection assays. The aim of this study was to develop a reliable PCR-based method to detect not only oqxA and oqxB but also any associations with IS26, allowing the detection of the transposon-associated oqxAB (Fig. 1A). The mobile version of oqxAB, which is embedded in Tn6010, has been almost exclusively reported on plasmids (10–13). To our best knowledge, only two Salmonella isolates carrying a chromosomally encoded OqxAB associated with IS26 have been reported so far (14). It is noteworthy that the transposon-borne version is associated with boosted expression because of the lack of rarA that normally downregulates oqxR and the presence of several plasmid copies of the plasmid-borne transposon version (7).

First, we carried out a multiplex conventional PCR to detect oqxA, oqxB, and an amplification product covering IS26 and oqxA. DNA extractions were all performed using the NucliSens easy-MAG (bioMérieux, Marcy l'Etoile, France), according to the manufacturer's recommendations. Multiplex PCRs were run using the MyCycler thermocycler (Bio-Rad, Marnes-la-Coquette, France). Amplicons of 222 bp, 127 bp, and 746 bp targeting oqxA, oqxB, and the region spanning the IS26 right end and oqxA 5′ terminus, respectively (Fig. 1A), were generated in a 50-µl PCR that con-

tained 5 µl of target DNA, 5 µl of PCR buffer, 0.5 µl of MgCl<sub>2</sub> (25 mM), 0.5 µl of deoxynucleoside triphosphate (dNTP) (25 mM), 25 or 100 pmol of each primer (Table 1), 0.5 µl of Tag polymerase  $(5 \text{ U/}\mu\text{l})$ , and 26.5  $\mu\text{l}$  of sterile water. The PCRs were run using the following temperature-time profile: 95°C for 3 min, 30 cycles of 94°C for 30 s, 52°C for 30 s, and 72°C for 1 min, followed by 72°C for 5 min. PCR products of the expected size were verified by electrophoresis in a 2% agarose gel. The control strains used for setting up the multiplex PCR were E. coli CSH26/pOLA52 (4), a clinical isolate of K. pneumoniae (KP10887) that we previously detected as positive for ogxAB (personal data), and E. coli CIP 54.8<sup>T</sup> as a negative control. An IS26-oqxA fragment specific to Tn6010 was amplified only in the plasmid-borne control E. coli CSH26/pOLA52 (Fig. 1B). The hybridization of I-CeuI pulsedfield gel electrophoresis (PFGE) profiles using an oqxB probe showed a chromosomal location only for *K. pneumoniae* KP10887 (15).

Second, we succeeded in setting up a simplex real-time PCR targeting each amplicon described above. These assays were carried out with the LightCycler 480 (Roche Molecular Diagnostics, Germany) using the same primers as described above (Table 1), with a PCR mix as follows: 2  $\mu$ l of target DNA, 10  $\mu$ l of 1× Kapa SYBR Fast quantitative PCR (qPCR) master mix (Kapa Biosystems, Wilmington, MA, USA), 0.4  $\mu$ l of each primer, and 7.2  $\mu$ l of sterile water. The PCR thermocycling program was as follows: 95°C for 7 min, followed by 40 cycles of 95°C for 10 s, 52°C for 30 s, and then melting resolution from 60°C to 98°C. As shown in Fig.

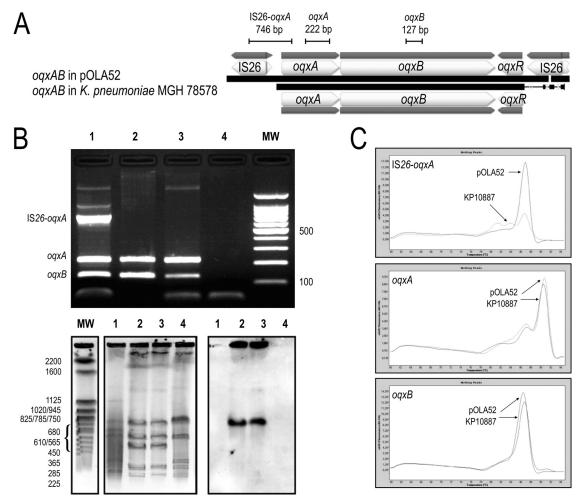

FIG 1 (A) Schematic representation of oqxAB carried in pOLA52 and K. pneumoniae strain MGH 78578 (GenBank accession no. NC\_009648.1). Lines indicate the size of the PCR fragments. (B) Top, agarose gel electrophoresis (2%) used for the separation of multiplex PCR products. Lane 1, E. coli CSH26/pOLA52; lanes 2 and 3, K. pneumoniae KP10887; lane 4, E. coli CIP 54.8<sup>T</sup>; MW, molecular weight marker (100-bp ladder; Invitrogen, Cergy-Pontoise, France). Bottom, PFGE migration profiles of I-CeuI restricted whole-cell DNAs. Lane 1, E. coli CSH26/pOLA52; lanes 2 and 3, K. pneumoniae KP10887; lane 4, E. coli CIP 54.8<sup>T</sup>; MW, E00 Saccharomyces cerevisiae chromosomes (Bio-Rad Laboratories, Hercules, CA, USA) used as a molecular weight marker. The set on the right shows hybridization performed with a specific probe for the e0 provides gene. (C) Derivative fluorescence melting curve (melting peak) for IS26-e0 paxA, e0 and e0 paxB green real-time PCR with LC480. The melting temperatures (e1, e2, e3 were 86.86°C, 90.79°C, and 86.16°C for IS26-e0 paxA, e1, and e2, e3, respectively.

1C, distinct peaks were clearly distinguished for each amplicon except IS26-oqxA for K. pneumoniae KP10887, demonstrating the absence of a neighboring IS26.

According to the prevalence of *oqxAB* (6, 16, 17), we proposed to combine our assays into a two-step strategy, with screening of *oqxAB* 

by detecting oqxB in real-time PCR and then determination of oqxAB location only on strains that were positive by multiplex PCR. This method was applied to (i) 25 *E. coli*, 25 *K. pneumoniae*, and 3 *Raoultella ornithinolytica* strains prospectively isolated from urine samples from patients hospitalized in our emergency room in Decem-

TABLE 1 Primers used in this study

<sup>&</sup>lt;sup>a</sup> Degenerate residues are underlined. All primers were designed using Geneious 7.1 (Biomatters Ltd., Auckland, New Zealand).

<sup>&</sup>lt;sup>b</sup> These primer concentrations were used for the multiplex PCR, while all primers were used at 25 pmol/reaction in the simplex real-time PCR.

ber 2014 and April 2015, (ii) 38 *E. coli* and 35 *K. pneumoniae* strains whose epidemiological links were studied previously (18), and (iii) the reference strains of the related genera *Klebsiella* and *Raoultella* (19) (*Klebsiella oxytoca* CIP 103434<sup>T</sup>, *K. pneumoniae* subsp. *ozaenae* CIP 52.211<sup>T</sup>, *K. pneumoniae* subsp. *pneumoniae* CIP 82.91<sup>T</sup>, *K. pneumoniae* subsp. *rhinoscleromatis* CIP 52.210<sup>T</sup>, *Klebsiella michiganensis* CIP 110787<sup>T</sup>, *Klebsiella singaporensis* CIP 108642<sup>T</sup>, *Klebsiella variicola* CIP 108585<sup>T</sup>, *R. ornithinolytica* CIP 103364<sup>T</sup>, *Raoultella planticola* CIP 100751<sup>T</sup>, and *Raoultella terrigena* CIP 80.7<sup>T</sup>). For all the strains with no detection of IS26-oqxA using our method, we confirmed the chromosomal location of oqxAB by amplifying a 1.3 kb-long fragment overlapping the upstream region of oqxA that matches with the chromosome and oqxA.

Among the *E. coli* clinical strains, we did not detect any *oqxAB* genes. However, all the clinical *K. pneumoniae* isolates (61/61) carried *oqxAB* without detection of Tn6010. Interestingly, all the *Klebsiella* sp. and *Raoultella* sp. reference strains carried *oqxAB* in their chromosome, indicating normal housekeeping functions in these specimens.

Norman et al. (5) have proposed that *K. pneumoniae* may be a reservoir for *oqxAB* and that an *oqxAB*-carrying plasmid, such as pOLA52, may have arisen by capture from the chromosome of *K. pneumoniae* recruited by IS26. Nonetheless, some studies failed to detect *oqxAB* in all the *K. pneumoniae* isolates studied (6, 16, 17). This raised the question of the chromosomal location of *oqxAB* in *K. pneumoniae*, which might be particular not only for capture from the chromosome but also for its ability to lose *oqxAB*. However, it is noteworthy that a lack of detection in previous studies might have resulted from inadequate primers.

The method we describe here led us to show that (i) all *Klebsiella* spp. (clinical, n=61; reference, n=7) and *Raoultella* spp. (reference, n=3) strains harbored oqxAB as part of their native chromosome, and (ii) the degenerate primers used in the present study allowed the detection of oqxAB in all cases. Moreover, our findings highlight the hypothesis stated by Norman et al. (5) and also demonstrate the importance of discriminating native and Tn6010-associated oqxAB regarding the overexpression of the mobile version.

## **ACKNOWLEDGMENTS**

We thank Janick Madoux from CHU Reims for her excellent technical assistance. We also thank Hélène Moret and Lydie Morcrette for their helpful discussion.

This work was supported by an annual grant from Université de Reims Champagne-Ardenne (EA 4687).
