15   *Abstract*

16   The evolution of signals and reproductive traits involved in the pre-mating recognition has  
17   been in focus of abundant research in several model species group such as bumblebees (genus  
18   *Bombus*). However, the most studied bumblebee reproductive trait, the male cephalic labial  
19   gland secretions (CLGS), remains unknown among bumblebee species from South America.  
20   In this study we investigated the CLGS of five South American bumblebees of the subgenera  
21   *Thoracobombus* (*Bombus excellens*, *B. atratus*) and *Cullumanobombus* (*B. rubicundus*, *B.*  
22   *hortulanus* and *B. melaleucus*) comparing their secretions to those of European closely related  
23   species. Our results show an obvious interspecific differentiation in all subgenera. The

24 interspecific differentiation in *Thoracobombus* involves different compounds with a large  
25 abundance (main compounds) while all *Cullumanobombus* share the same main components.  
26 This suggests that in *Cullumanobombus* subgenus differentiation in minor components could  
27 lead to species discrimination.

30 **Introduction**

31 The pre-mating communication is of particular interest for evolutionary biologists because  
32 of its key role in sexual selection [1,2]. Therefore, the evolution of signals and reproductive  
33 traits involved in the pre-mating recognition has been widely studied [3] in several model  
34 species groups such as birds (e.g., [4–6]), moths (e.g. [7–9]) flies (e.g., [10–12]), or more  
35 recently the bumblebees (e.g., [13–15]).

36 The pre-mating recognition of bumblebees (genus *Bombus*) includes both chemical and  
37 behavioral features [16]. Most bumblebee males patrol along paths (i.e. patrolling behavior)  
38 where they scent-mark objects with their cephalic labial gland secretions (CLGS) [17,18] that  
39 attract conspecific virgin females [13,19]. Other species exhibit less common behavior as  
40 perching behavior, in which males wait individually at prominent places and dart passing  
41 queens or other moving objects [20]. The CLGS is a complex mixture of (mainly aliphatic)  
42 compounds[18,21,22] produced *de novo* by the cephalic labial glands (acinar gland) [23] from  
43 saturated fatty-acids [24,25]. The resulting composition is species-specific [18]. The CLGS  
44 are thus an excellent tool for exploring interspecific and intraspecific variations of pre-mating  
45 recognition [13–15,26] as well as they are useful chemo-taxonomic characters [22,27–29].

46 Despite the usefulness of the CLGS as model in evolutionary biology and taxonomy, the  
47 male chemical secretions of a great number of species remain unknown [13]: the CLGS have  
48 been described for 50 species of a total of approximately 250 bumblebee species [30]. In  
49 several biogeographic regions such as South America, no studies have been published.  
50 Indeed, the CLGS chemical analyses require fresh samples [31] that are most of the time  
51 unavailable for uncommon taxa. In this paper, we investigated, the CLGS of males of five  
52 South American bumblebees: *Bombus melaleucus* Handlirsch, 1888 and *B. hortulanus* Friese,  
53 1904 are near species belonging to the "Robustus group"(= *Robustobombus* sensu Richards,  
54 1968 [32]) while *B. rubicundus* Smith, 1854 (Fig. 1 D) belongs to "Rubicundus group"(=  
55 *Rubicundobombus* sensu Richards, 1968 [32]), these species-groups being now included in  
56 *Cullumanobombus* subgenus [33]. *B. atratus* Franklin, 1913 (Fig. 1 B) and *B. excellens*  
57 Smith, 1879 (Fig. 1 A) both belong to the "Fervidus-species group"(= *Fervidobombus* sensu  
58 Richards, 1968 [32]) now all included in *Thoracobombus* subgenus [33]. We ultimately aim  
59 to compare their CLGS composition with those of related species from the same subgenus: *B.*  
60 (*Thoracobombus*) *muscorum liepetterseni* (L. 1758), *B.* (*Thoracobombus*) *pascuorum*  
61 *melleofacies* Vogt, 1911, *B.* (*Cullumanobombus*) *cullumanus apollineus* Skorikov, 1910 (Fig.  
62 2 C) and *B.* (*Cullumanobombus*) *semenoviellus* Skorikov, 1910.

### 63 **Results and discussion**

#### 64 *Composition of cephalic labial gland secretions*

65 Chemical analyses detected 146 compounds (33 from *B. excellens*, 35 from *B. atratus*, 53  
66 from *B. pascuorum*, 19 from *B. muscorum*, 16 from *B. rubicundus*, 22 from *B. hortulanus*, 39  
67 from *B. melaleucus*, 22 from *B. cullumanus* and 44 from *B. semenoviellus* ) (see *Table 1*). The  
68 results showed that all *Thoracobombus* species were differentiated in their CLGS composition  
69 (seven compounds shared by all species and 17 compounds shared between the two South

70 American species), including changes in main compounds (octadec-11-enol (29% - 46%) in  
71 *B. excellens* and octadec-9-enol (54% - 91%) in *B. atratus* (*Table 1*). Inside the European  
72 taxa, hexadec-7-enol (10% - 31%) in *B. pascuorum* and octadec-9-enyl acetate in *B.*  
73 *muscorum* were the major compounds (*Table 1*). By main compounds of a taxon, we mean  
74 every compound that has the highest relative amount within the CLGS at least in one  
75 individual. Other differences between the South American *Thoracobombus* were mainly  
76 qualitative differences in minor compounds (*Table 1*). Similarly, the *Cullumanobombus*  
77 species displayed qualitative differences (only five compounds shared; six compounds shared  
78 between the three South American *Cullumanobombus*), but the main compound,  
79 geranylgeranyl acetate, is in common to all *Cullumanobombus* analyzed here: 81% - 94% in  
80 *B. rubicundus*, 76% - 83% in *B. hortulanus*, 18% - 59% in *B. melaleucus*, 51% - 92% in *B.*  
81 *cullumanus* and 37% - 60% in *B. semenoviellus*. Qualitative variations differentiated species  
82 in minor components (*Table 1*).

83 *Statistical analysis*

84 For both *Thoracobombus* and *Cullumanobombus* groups, the statistical analyses of the CLGS  
85 confirmed the interspecific differentiation (Fig. 2). This chemical differentiation is supported  
86 by high values of multiscale bootstrap resampling (> 80%, Fig. 2). The interspecific  
87 differentiations between all consubgeneric species observed in our results are in agreement  
88 with the species-specificity of CLGS observed in other bumblebee groups (e.g.,  
89 [18,22,27,29]). Similarly to our results on *Thoracobombus* species, the comparison of CLGS  
90 between closely related bumblebee taxa with a commonly recognized species status allow  
91 suggesting that the interspecific differentiation involves the change in main compounds (e.g.,  
92 [18,29,34]). These main compound differentiations can be (i) a significant shift (production of  
93 new types of compounds, e.g., *B. pascuorum* versus *B. muscorum*) consecutive to switching  
94 off and on the respective metabolic pathway (e.g., [7]), (ii) large increase of a minor

95 compound shared with closely related species (e.g., octadec-9-enyl acetate between *B.*  
96 *muscorum* versus *B. atratus*) [35], as well as (iii) difference in double bound position arisen  
97 by activity of different enzymes (e.g.,  $\Delta$ 11-desaturase and  $\Delta$ 9-desaturase introducing a double  
98 bound in octadecenol in *B. excellens* and *B. atratus*, e.g., [8]) or by activation of a non-  
99 functional enzyme gene transcript present in a common ancestor, as observed in moths [9] and  
100 in other bumblebees [15]. In contrast, all *Cullumanobombus* species display the same main  
101 component (geranylgeranyl acetate) as observed in the North American *B.*  
102 (*Cullumanobombus*) *rufocinctus* Cresson, 1863 [20]. The geranylgeranyl acetate is also a  
103 main component of *Bombus* (*Alpigenobombus*) *wurflenii* [36], *B.* (*Kallobombus*) *soroensis*  
104 [37] and *B.* (*Separatobombus*) *griseocollis* [38] meaning that this component could not be  
105 considered as autapomorphic of *Cullumanobombus*. Assuming the key role of CLGS in pre-  
106 mating recognition, this suggests that differentiation in minor compounds could lead to  
107 species discrimination. Moreover, for each CLGS group, the IndVal method revealed several  
108 significantly indicator compounds (see supplementary file 1).

109 **Conclusion**

110 The cephalic labial gland secretions of males are widely acknowledge as a useful and  
111 practical diagnostic trait for bumblebee species. Among the European bumblebee fauna,  
112 several taxonomically doubtful taxa groups have been solved thank to this reproductive trait.  
113 The present study is the first study to examine this trait among South American bumblebee  
114 species. This paves the way to a massive taxonomic assessment of South American  
115 bumblebees.

122 *Acknowledgement*

123 The authors sincerely thank Peter Neumann (University of Bern, Switzerland) for his help in  
124 providing contact for collecting the biological material. Financial support (IV and KU) was  
125 provided by the Institute of Organic Chemistry and Biochemistry of the Academy of Sciences  
126 of the Czech Republic (subvention for development of research organization RVO:  
127 61388963). TL is post-doc in the context of the BELBEES project funded by the Belgian  
128 Scientific Politic (BELSPO, BR/132/A1/BELBEES). The authors acknowledge the *Fonds*  
129 *pour la recherche dans l'industrie et l'agriculture* (FRIA) for financial support (Project  
130 2.4.564.06 F). Field trips of PR and TL in Sweden, Italy and in Turkey to collect material  
131 have been funded by the Belgian FNRS. Thanks to B. Cederberg (Uppsala) and A.M. Aytekin  
132 (Ankara) for their help. Special thanks to R. de Jonghe for the breeding of *B. muscorum*  
133 *liepetterseni* males and to Nicolas R. Chimento (Laboratorio de Anatomía Comparada y  
134 Evolución de los Vertebrados Museo Argentino de Ciencias Naturales "Bernardino  
135 Rivadavia") for providing us pictures of *Bombus atratus*.

147

148    **Experimental part**

149    *Biological material*

150    Fifty males from two subgenera were used for this study (*Table 2*): *B. melaleucus* (n=2), *B.*  
151    *hortulanus* (n=3), *B. rubicundus* (n=7), *B. atratus* (n=12), and *B. excellens* (n=2). As  
152    comparison group of *Thoracobombus* we used specimens already described in Lecocq *et al.*  
153    [28]: *B. muscorum liepetterseni* (n=5), *B. pascuorum melleofacies* (n=7). We used *B.*  
154    *cullumanus apollineus* (n=9) and *B. semenoviellus* (n=3) already described in [39] as  
155    comparison group of *Cullumanobombus*. We killed specimens by freezing at -20°C. The  
156    CLGS were extracted in 400 ml of hexane [31]. Samples were stored at -40°C prior to the  
157    analyses.

158    *Chemical analyses*

159    We identified the CLGS composition by gas chromatography-mass spectrometry (GC/MS) on  
160    a quadrupol Finigan GCQ, with a DB-5ms non-polar capillary column (5% phenyl (methyl)  
161    polysiloxane stationary phase; 30-m column length; 0.25-mm inner diameter; 0.25- $\mu$ m film  
162    thickness). One  $\mu$ l was injected in splitless mode at the injector temperature set to 220°C. The  
163    temperature of the column was initially held to 70°C for two minutes and then increased at a  
164    rate of 10°C/min to 320°C. The temperature was then held at 320°C for five minutes. The  
165    carrier gas was helium at a constant velocity of 50 cm/s. Compounds were identified using the  
166    retention times and mass spectra of each peak. Double bound positions were determined by  
167    DMDS (dimethyl disulfide) derivatization [40].

168    We analyzed all samples by a gas chromatograph-flame ionization detector Shimadzu GC-  
169    2010 with a SLB-5ms non-polar capillary column (5% phenyl (methyl) polysiloxane

170 stationary phase; 30-m column length; 0.25-mm inner diameter; 0.25- $\mu$ m film thickness) with  
171 the same chromatographic conditions as in GC/MS.

172 Peak areas of compounds were detected in GCsolution Postrun (Shimadzu Corporation) with  
173 automatic peak detection and noise measurement. We calculated relative amounts (RA in %)  
174 of compounds in each sample by dividing the peak areas of compounds by the total area of  
175 compounds in each sample. We did not use any correction factor to calculate the RA of  
176 individual compounds. We discarded all compounds for which RA were recorded as less than  
177 0.1% for all specimens [31]. We elaborated the data matrix as the alignment of each  
178 compound between all samples performed with GCAigner 1.0 [41,42]( see supplementary  
179 file 1).

180 *Statistical analyses*

181 Statistical analyses were performed using R [43] to detected CLGS differentiations between  
182 specimen groups. Data consisting of the relative proportion of all compounds were  
183 transformed ( $\log(x-1)$ ) to reduce the large difference of abundance between highly and  
184 slightly concentrated compounds, and we then standardized (mean= 0, standard deviation= 1)  
185 the data matrix to reduce the sample concentration effect [22]. Clustering method was used to  
186 detect the divergence between taxa. A Pearson Phi Correlation matrix based on CLGS data  
187 matrix (relative abundance of each compound) was computed. An unweighted pair group  
188 method with arithmetic mean (UPGMA) was used as clustering method (R-package ape,[44]).  
189 We assessed the uncertainty in hierarchical cluster analysis using *p*-values calculated via  
190 multiscale bootstrap resampling with 50.000 bootstrap replications (R-package pvclust,[44]).  
191 Only bootstrap values greater than 85% were considered significant. To determine  
192 compounds of each taxa (indicator compounds), we used the indicator value (IndVal) method  
193 [45,46]. The value given is the product of relative abundance and relative frequency of

194 occurrence of a compound within a group. We evaluated the statistical significance of a  
195 compound as an indicator at the 0.01 level with a randomization procedure.

305 *Table*

306 Table 1. *List of the identified compounds in the Thoracobombus and Cullumanobombus subgenera.* Molecular Weight (MW), median (M [%]) of  
 307 the 146 identified compounds. For each species, main compounds are shown on black background, characteristic compounds calculated with the  
 308 Indicator value (IndVal) method (>0.70) are shown in grey background. The compounds we were not able to determine are indicated as *Ux*. The  
 309 full table with first and fourth quartile (Q1 and Q4 [%]) are in the supplementary file 1

310

Compounds	MW	<i>B. atratus</i>	<i>B. excellens</i>	<i>B. pascuorum</i>	<i>B. muscorum</i>	<i>B. hortulanus</i>	<i>B. melaleucus</i>	<i>B. rubicundus</i>	<i>B. cullumanus</i>	<i>B. semenoviellus</i>
