20

21 **ABSTRACT**

22 Camelid α -lactalbumin is the only known protein that can undergo nonenzymatic deamidation on
23 two Asn residues. This leads to the generation of a mixture of unusual iso-Asp and D-Asp residues
24 that may impact health. The effect of deamidation on camel α -lactalbum instability was investigated.
25 Circular dichroism showed that the altered protein acquired secondary structure resulting in an
26 increase in α -helix content. In good agreement, the 3D structure of camel α -lactalbumin determined

27 by X-ray crystallography, displayed a short additional α -helix probably induced by deamidation,
28 compared to the human and bovine counterparts. This α -helix was located in the C-terminal region
29 and included residues 101 to 106. Differential scanning calorimetry together with the susceptibility
30 to thermolysin showed that the deamidation process reinforced the structural stability of the α -
31 lactalbumin at high temperature and its resistance toward proteolysis.

32

34 liquid chromatography; HAMLET, human α -lactalbumin made lethal to tumor cells; HPLC, high-performance liquid
35 chromatography; PAGE, polyacrylamide gel electrophoresis.

36

37 **1. Introduction**

38

39 Nonenzymatic deamidation of proteins has been studied extensively *in vivo* and *in vitro*
40 because of its important biological effects on enzymatic activity, folding, and proteolytic
41 degradation, and also because of its crucial role as a molecular clock *in vivo* (Aswad, Paranandi &
42 Schurter, 2000; Robinson & Robinson, 2004). The side chain of Asn residues is prone to deamidate
43 under physiological conditions (i.e. near-neutral or slightly basic pH and 37 °C), especially when the
44 adjacent residue at the C-terminal side is Gly. However, ordered secondary structures such as α -
45 helices and β -sheets inhibit the process, as the peptide backbone and the side chains are stabilized by
46 numerous hydrogen bonds (Robinson & Robinson, 2004). This post-translational modification leads
47 to the production of a mixture of L-isoAsp, L-Asp, D-isoAsp, and D-Asp residues in the polypeptide
48 chain (Aswad et al., 2000).

49 Intriguingly, a few dietary proteins, especially from milk of some species, are readily subject
50 to nonenzymatic deamidation at the level of their Asn-Gly sequences: women's milk lactoferrin
51 (Belizy et al., 2001), equine α -lactalbumin (α -La; Girardet et al., 2004) and β -casein (Girardet,
52 Miclo, Florent, Mollé, & Gaillard, 2006), canine milk lysozyme (Nonaka et al., 2008), bovine β -

53 lactoglobulin B (Meltretter, Wüst, & Pisc, 2013), and more recently in our previous work, we have
54 identified two deamidated isoforms of *camelus dromedarius* α -La by Fourier transform ion cyclotron
55 resonance mass spectrometry and shown that Asn⁴⁵ is deamidated spontaneously at pH 7.4 and 37
56 °C, whereas Asn¹⁶ needs a more basic pH higher than 8.0 to undergo a deamidation process (Si
57 Ahmed Zennia et al., 2015). Among the investigated α -LAs, that of the *Camelidae* family (camel,
58 guanaco, and llama) has the particularity to be the only known α -La with two Asn-Gly motifs at
59 positions 16–17 and 45–46. However, whatever the species studied, the biological significance of
60 nonenzymatic deamidation of dietary proteins remains unknown. Si Ahmed Zennia et al. (2015)
61 assumed that the formation of isoAsp in the gut after camel milk-derived food intake might elicit
62 auto-immunity (Aswad et al., 2000) and might be responsible of IgE-mediated allergy as reported by
63 Gall, Kalveram, Sick, and Sterry (1996) after equine milk consumption.

64 The α -La protein is a subunit of the lactose synthase complex that promotes the synthesis of
65 lactose in the mammary gland in response to prolactin (Kuhn, Carrick, & Wilde, 1980). It contains
66 123 amino acid residues and its compact, globular structure is stabilized by four disulfide bonds and
67 by the presence of a calcium ion (holo form). The globular structure of α -La is composed of a large
68 α -domain (regions 1–34 and 86–123) containing three α -helices and two 3_{10} helices, and a small β -
69 domain (region 35–85) containing a three-stranded antiparallel β -sheet and a 3_{10} helix (Chandra,
70 Brew, & Acharya, 1998; Chrygina, Brew, & Acharya, 2000). Besides, the 99–114 region forms a
71 flexible loop located between α -helix α_3 (region 86–98) and the 3_{10} helix h2 (region 115–118). The
72 calcium-binding loop including Asp⁸², Asp⁸⁷, and Asp⁸⁸ is located at the junction of the α - and β -
73 domains and this explains why the presence of one calcium ion strongly stabilizes the protein
74 (Chrygina et al., 2000). Calcium binding confers a relative resistance to enzyme proteolysis and
75 different strategies to remove calcium are being developed to increase the susceptibility of α -La
76 towards proteases, such as acidification (Schmidt & Poll, 1991), heat treatment (N'Negue et al.,
77 2006), or zinc ion binding (Permyakov & Berliner, 2000). In the absence of calcium (apo form), the
78 protein adopts a molten globule state sensitive to proteolysis. The molten globule is defined by a

79 partly unfolded, reversible structure for which the 3D structure is poorly defined whereas the
80 secondary structure remains unchanged (for review see Ptitsyn, 1995).

81 The α -La protein displays many biological properties. In human, apo- α -La, in molten globule
82 state, can form a complex with oleic acid (C18:1 ω 9-*cis*), thus acquiring a tumoricidal activity
83 against cancer cells of different origin. This complex is known as HAMLET (for human α -
84 lactalbumin made lethal to tumor cells; Ho, Nadeem, & Svanborg, 2017). Similarly, camel α -La is
85 able to bind oleic acid and acquires cytotoxic effect vs. human prostate cancer cells (Atri et al., 2011)
86 or breast cancer cells (Uversky, El-Fakharany, Abu-Serie, Almehdar, & Redwan, 2017). In cow's
87 milk, α -La is considered as the least allergenic milk protein (Natale et al., 2004), contrary to β -
88 lactoglobulin, which is the most abundant soluble protein and one of the major milk allergens
89 responsible for cow milk allergy (Wu et al., 2018). The camel milk has the particularity to be free of
90 β -lactoglobulin and therefore, α -La is the most abundant among the soluble proteins (higher than 5
91 g/L, Alavi, Salami, Emam-Djomeh, & Mohammadian, 2017). Another advantage of camel α -La is
92 its antioxidant power, more efficient than that of bovine α -La (Salami et al., 2009). Besides, the
93 camel α -La possesses a nutritional interest, as it contains a high concentration of essential amino
94 acids in agreement with its polypeptide sequence (Swiss-Prot accession number P00710), slightly
95 higher than the bovine counterpart, as noticed by Salami et al. (2009).

96 The degree of hydrolysis obtained by trypsin (E.C. 3.4.21.4) or chymotrypsin (EC 3.4.21.2)
97 treatment is higher with camel α -La than with bovine α -La (Salami et al., 2009). This is explained
98 by conformational and structural differences between the two homologous proteins, as shown by
99 fluorescence measurements performed by Salami et al. (2009). Despite the attractive nutritional
100 value of α -La, low digestibility is reported for this protein, especially in the stomach the pH of which
101 is 5–6 during a milk intake, preventing the action of pepsin (E.C. 3.4.23.1) which has an optimal
102 activity at ca. pH 1–2 (Lindberg, Engberg, Sjöberg, & Lönnerdal, 1998). According to Salami et al.

103 (2009), in the gut trypsin and chymotrypsin play a critical role to digest α -La, the camel protein
104 appearing more sensitive than the bovine counterpart.

105 More generally, interest for camel milk use in human nutrition has increased during the last
106 decade, as evidenced by many review-articles that report nutraceutical potential and health benefits
107 of this milk. For instance, camel milk is used for therapeutic properties efficient against diabetes and
108 cancer as well as for anti-hypertensive and anti-oxidative properties (for recent review, see Sakandar
109 et al., 2018).

110 The present work focuses on *in vitro* studies of the structural stability of the main camel whey
111 protein, namely α -La, susceptible to undergo a deamidation phenomenon, especially in the gut after
112 a milk intake. This nonenzymatic deamidation, not observed for the bovine protein, might change the
113 stability of camel α -La and have an incidence on the bioavailability in the gastrointestinal tract and
114 thus on its biological activity and nutritional properties. The investigations were performed by using
115 circular dichroism and X-ray crystallography, as well as differential scanning calorimetry and finally
116 studies concerning susceptibility to proteolysis.

117

118 **2. Materials and methods**

119 *2.1. Materials*

120

121 The ÄKTA-Purifier system and the Superdex 75 column were from GE Healthcare (Uppsala,
122 Sweden), the Amicon™ concentration cell was purchased from Merck Millipore (Darmstadt,
123 Germany), the spectropolarimeter CD6 was from Jobin-Yvon (Palaiseau, France) and the X8-
124 Proteum diffractometer was from Bruker AXS (Madison, WI, USA). The Microcal VP-DSC device
125 was purchased by Malvern Instruments, Malvern, UK). The Alliance 2690 unit was from Waters
126 (Milford, MA, USA) and the LichroCart C₁₈ column (250 x 4 mm, 5 μ m particle size, 10 nm
127 porosity) was from Merck (Darmstadt, Germany). All the chemicals, reagents and enzymes were
128 purchased from Sigma Chemical Co. (St. Louis, MO, USA).

129

130 2.2. Nonenzymatic deamidation of α -La and purification of isoforms

131

132 Raw milk was obtained from a herd of Sahraoui female dromedaries (*Camelus dromedarius*)
133 and immediately stored at -20 °C until use. The pH of the fresh milk sample was 6.7. After skimming
134 the milk by centrifugation (3500 g at 32 °C for 30 min), the casein fraction was discarded by
135 precipitation at pH 4.3 with 1 M HCl and centrifugation. The supernatant was neutralized with 1 M
136 NaOH, dialyzed against ultra-pure water at 4 °C for 72 h and the soluble protein fraction was freeze-
137 dried.

138 The soluble protein fraction was dissolved at 15 mg/mL in 150 mM sodium phosphate buffer,
139 pH 8.4 (in the presence of 0.02% sodium azide as preservative), filtered at 45 μ m, and incubated at
140 37 °C for 96 h. After incubation, the mono-deamidated (A₂) and di-deamidated forms (A₃) were
141 purified from the soluble protein fraction by anion-exchange fast protein liquid chromatography
142 (FPLC) performed with an ÄKTA-Purifier system according to the method of Si Ahmed Zennia et
143 al. (2015). The native form (A₁) was also purified by anion-exchange FPLC, but from the soluble
144 proteins that had not been incubated at 37 °C. The recovered α -La isoforms were then checked for
145 purity by native polyacrylamide gel electrophoresis (PAGE performed under non-reducing and non-
146 denaturing conditions) as described (Si Ahmed Zennia et al., 2015). The three isoforms were desalted
147 by size exclusion chromatography onto a Superdex 75 column connected to the ÄKTA-FPLC system
148 stored in a refrigerated cabinet maintained at 4 °C, and finally concentrated with an Amicon™
149 concentration cell.

150

151 2.3. Circular dichroism of α -La isoforms

152

153 The circular dichroism (CD) spectra were recorded with a spectropolarimeter CD6 equipped
154 with a thermostatic cell holder (25 °C), using 1.0-mm path length quartz cell. CD spectra were

155 acquired with 20-nm/min scan speed at 0.2 nm step size and 1.0-nm bandwidth under constant
156 purging with nitrogen. Changes in the secondary structures of deamidated forms of camel α -La were
157 monitored in the far-UV region (190–260 nm) at final protein solutions concentration of 36, 63 and
158 76 μ M for A₁, A₂, and A₃ isoforms, respectively. Near-UV CD (260–320 nm) spectra were recorded
159 using the same parameters with final protein concentrations of 3.60, 12.70 and 7.65 μ M for A₁, A₂,
160 and A₃ isoforms, respectively. The concentration of protein solutions was measured
161 spectrophotometrically using an extinction coefficient of $\epsilon = 32,470 \text{ M}^{-1} \text{ cm}^{-1}$ at 280 nm. The buffer
162 was sodium phosphate 10 mM, pH 7.4. Three spectra were accumulated and averaged for each
163 sample. The baseline obtained with buffer was subtracted from each spectrum and the resultant
164 values were adjusted to the concentration when mdeg expressed raw data were converted to mean
165 residue ellipticity $[\theta]$ expressed in $\text{deg cm}^2 \text{ dmol}^{-1}$, based on a mean amino acid residue molecular
166 mass (m) of 113 Da. The mean residue ellipticity was defined as:

167

$$168 \quad [\theta]_{\lambda} = 100 m \theta_{\text{obs}} c/l \quad (1)$$

169

170 where θ_{obs} is the observed ellipticity in degrees at a given wavelength, c is the protein concentration
171 in mg/mL and l is the length of the cell (cm). Secondary structure estimation from the far-UV CD
172 spectra was calculated using the software CDNN (Böhm, Muhr, & Jaenicke, 1992).

173

174 *2.4. Crystal structure of camel α -La*

175 *2.4.1. Crystallization and X-ray data collection*

176

177 Crystals of camel α -La were grown by vapor diffusion in hanging drops according to Ducruix
178 and Giegé (1999). Drops were made at 293 K by mixing 2 μ L of the protein solution at 45 mg/mL
179 and 3 μ L of a reservoir solution containing 20% polyethylene glycol PEG 6000, 2 mM zinc chloride,

180 and 100 mM Tris at pH 8.0. The obtained crystals belong to space group $P3_121$ with unit-cell
181 parameters $a = 52.2 \text{ \AA}$, $b = 52.2 \text{ \AA}$, and $c = 75.5 \text{ \AA}$. Assuming one monomer in the asymmetric unit,
182 the packing density V_M is $2.06 \text{ \AA}^3 \cdot \text{Da}^{-1}$ and the solvent content is 40.3%. Crystals were flash frozen
183 in liquid nitrogen in the mother liquor with addition of 20% glycerol as cryoprotectant. A native data
184 set at 1.93-\AA resolution was collected in our laboratory at 100 K on an X8-Proteum diffractometer,
185 with incident radiation at a wavelength of 1.542 \AA . The crystal-to-detector distance was 40 mm with
186 0.5° oscillation per CCD image. Data were processed using the X8-Proteum^{Plus} software from Bruker
187 AXS.

188

189 2.4.2. Crystal structure determination

190

191 The crystal structure of the camel α -La was solved by molecular replacement with the
192 program PHASER (McCoy et al., 2007) using the coordinates of the human α -La (Chandra et al.,
193 1998; PDB 1A4V). Building of the model was performed using Coot (Emsley, Lohkamp, Scott, &
194 Cowtan, 2010), and the refinement of the crystal structure was performed in the range $10\text{--}1.93 \text{ \AA}$
195 using REFMAC5 (Vagin et al., 2004). A total of 10% of the native data were selected for R_{free}
196 calculations. The model was refined to the final R_{factor} of 19.5% and R_{free} of 26.8% (Table S1) and
197 includes residues 1–43, 46–65, and 68–120 of the camel α -La, as well as 84 water molecules, one
198 calcium ion, and one zinc ion. Because of the lack of density, residues 44–45, 66–67, and 121–123 of
199 the camel α -La were not built. Over 96% of the residues were within the most favored regions, and
200 no residue was within the disallowed regions in a Ramachandran plot, as defined by PROCHECK
201 (Laskowski, McArthur, Moss, & Thornton, 1993).

202

203 2.5. Differential scanning calorimetry of α -La isoforms

204

205 Differential Scanning Calorimetry (DSC) experiments were performed on a Microcal VP-
206 DSC apparatus equipped with 0.54-mL cells, at pressure of 2 atm. The thermograms were recorded
207 using the isoforms A₁, A₂ and A₃ of α -La at a 0.5 mg/mL (35 μ M) in 10 mM acetate buffer pH 6.0.
208 A scanning window from 20 to 100 °C with a constant scan rate of 1 °C/min was applied. Origin 7.0
209 software was used to determine the T_m (midpoint of the unfolding transition) and the ΔH_{cal}
210 (calorimetric enthalpy). Except for the A1 isoform, reversibility of unfolding was observed when the
211 samples were rescanned after heating to 100 °C. Baselines recorded with both cells filled with buffer
212 were subtracted from the experimental traces to obtain the heat capacity curves (ΔC_p , excess heat
213 capacity, vs. temperature). The thermodynamic data were the average of three scans and results were
214 expressed as the mean \pm SD. Statistical analysis was performed with GraphPad Prism 5 using one-
215 way ANOVA method followed by Bonferroni's multiple comparison test.

216

217 2.6. Susceptibility of α -La isoforms to thermolysin hydrolysis

218

219 Hydrolysis of the camel α -La isoforms A₁, A₂, and A₃ by thermolysin (EC 3.4.24.27) was
220 carried out according to N'Negue et al. (2006). The α -La isoforms (A₁, A₂, and A₃) were solubilized
221 at 1 mg/mL (70 μ M) in 50 mM 2-[4-(2-hydroxyethyl)-1-piperazine] ethanesulfonate buffer, pH 7.2,
222 containing 10 mM CaCl₂ and 0.02% sodium azide. An appropriate aliquot of thermolysin from
223 *Bacillus thermoproteolyticus rokko* was added to 1 mL of each α -La isoform solution to obtain an
224 enzyme-to-substrate molar ratio of 1/80. The reaction was carried out at 37 °C for 30 to 180 min and
225 was stopped by adding 2% trifluoroacetic acid which decreased the pH to 1.0. The characterization
226 of the hydrolyzates obtained from each α -La isoform was performed by reversed-phase high-
227 performance liquid chromatography (HPLC) onto a LichroCart C₁₈ column connected to an Alliance
228 2690 unit according to N'Negue et al. (2006). Bovine α -La, purified from raw milk as previously
229 described (N'Negue et al., 2006), was used as the reference in the same experimental conditions.

230

231 **3. Results and discussion**

232

233 In a previous work (Si Ahmed Zennia et al., 2015), we unveiled that camel α -La (Swiss-Prot
234 accession number P00710) is subject to nonenzymatic deamidation at its two Asn-Gly motifs, Asn⁴⁵
235 being more readily deamidated than Asn¹⁶ for which a more basic pH is needed for the generation of
236 the deamidated form. Besides, we demonstrated that the two variants reported in the earlier literature
237 correspond in fact to native isoform (A₁) and to mono-deamidated isoform at position 45 (A₂). No di-
238 deamidated isoform (A₃) was observed in the early reports. The present paper focuses on the impact
239 of deamidation on the structure of camel α -La, this nonenzymatic modification being the most
240 extensive among all α -Las susceptible to deamidation.

241 The three isoforms were prepared by anion-exchange FPLC with high purity as shown by
242 native PAGE analysis (Fig. 1). Their identification was performed by determination of their
243 respective molecular masses in our previous work (Si Ahmed Zennia et al., 2015). Differences in
244 molecular masses between A₁ and A₂, and between A₂ and A₃ are 0.991 and 0.984 Da, respectively,
245 that corresponds to the replacement of one primary amine function by one hydroxyl function in the
246 case of deamidation of one Asn residue. Besides, the calcium ion naturally bound to the protein was
247 preserved during the chromatographic purification step performed under nondenaturing conditions.
248 Indeed, Girardet et al. (2004) showed that the addition of ethylenediaminetetraacetate (EDTA, strong
249 chelator of calcium) to equine α -La leads to release of calcium ion, observed electrophoretically by a
250 band shift of the α -La, deamidated or not (higher migration rate). Thus, the native and deamidated α -
251 La isoforms are still in their holo form after their purification. Two other studies (Salami et al., 2009;
252 Atri et al., 2010) have also purified the holo form of camel α -La without loss of calcium ion during
253 the process (ammonium sulfate precipitation and ultrafiltration). In fact, the calcium ion strongly
254 binds to α -La with an affinity constant of $3 \times 10^8 \text{ M}^{-1}$ for human α -La (Permyakov & Berliner,
255 2000).

256 The secondary and tridimensional structures of A₁, A₂, and A₃ were investigated by CD in the
257 far- and near-UV regions (Fig. 2). The near-UV CD spectra had the typical features of the spectrum
258 of holo- α -La with a minimum in the region 270–275 nm (corresponding to Tyr) and a maximum at
259 292 nm for Trp (Girardet et al., 2004; N’Negue et al., 2006; Saricay, Wierenga, & de Vries, 2014).
260 According to former studies, the spectrum of apo- α -La is different but nevertheless retains the
261 characteristic shape of the spectrum of the holo- α -La with much lower intensity (Saricay et al.,
262 2014), or is featureless (N’Negue et al., 2006). However, the peak at 292 nm was not well-resolved
263 in the case of the camel α -La, because the signal related to 5 Trp (the camel protein contains an extra
264 Trp) is stronger around 300 nm than the signal due to only 4 Trp in the case of bovine α -La
265 (N’Negue et al., 2006; Saricay et al., 2014) or equine α -La (Girardet et al., 2004). On the other hand,
266 the spectra of the three isoforms were similar suggesting that the single deamidation as well as the
267 double deamidation had no significant effect on the 3D structure of camel α -La, or as no aromatic
268 amino acid is sufficiently close to the deamidation sites, no disturbance of the aromatic amino acid
269 environment was detected.

270 The far-UV spectra of A₁, A₂, and A₃ corresponded to ordered secondary structures with
271 more than 52% of α -helices and β -strands (Table 1). The shapes of the spectra were similar to those
272 determined by Salami et al. (2009) and Atri et al. (2010) for camel holo- α -La in native state. When
273 the protein became deamidated, the ellipticity at 222 nm increased, that could be interpreted by an
274 increase of α -helix content upon deamidation (Greenfield, 2006). The deamidation of Asn⁴⁵ (isoform
275 A₂) seemed to be the one that caused the most pronounced conformational change with this particular
276 gain in α -helix secondary structure. The extra deamidation of Asn¹⁶ (in A₃) did not seem to modify
277 more significantly the conformation at the secondary structure level. It is worthy to note that the
278 secondary structure content of A₂ is very close to that of the camel α -La in Atri et al. (2010),
279 suggesting that the reported protein is perhaps mono-deamidated. Besides, the secondary structure
280 content of A₂ was also close to that of its bovine counterpart (Atri et al., 2010).

281 In order to deepen the structural investigations, we determined the 3D structure of the camel
282 α -La at atomic resolution by X-ray crystallography. The overall fold of the camel α -La (Fig. 3a) is
283 similar to the 3D structure of other α -La from various species. For instance, the superimposition of
284 the 3D structure of the camel α -La with the crystal structures of the human α -La (Chrysina et al.,
285 2000) and the bovine α -La (Chandra et al., 1998) yielded a root-mean-square deviation of C α
286 positions of 0.79 Å and 0.83 Å, respectively. The crystal structure of the camel α -La revealed the
287 presence of one calcium ion at the surface of the protein. This calcium binding-site was identical to
288 that found in the crystal structures of human and bovine α -Las and involved side-chains of Asp⁸²,
289 Asp⁸⁷ and Asp⁸⁸. As the solution used for the crystallization of the camel α -La did not contain
290 calcium ions (see Materials and Methods), the calcium ion was not lost during the chromatography
291 purification step and the camel α -La was still in its holo form after purification. The crystals of
292 camel α -La that were used for X-ray structure determination, were obtained from pure α -La isoform
293 A₁ (no deamidation) in a solution containing 100 mM Tris at pH 8.0. As the Asn⁴⁵ from camel α -La
294 was shown to deamidate spontaneously at pH 7.4 whereas Asn¹⁶ needs a more basic pH upper to 8.0
295 to undergo a deamidation process (Si Ahmed Zennia et al., 2015), a native PAGE analysis of the
296 crystals was performed to determine which α -La isoform was preferentially crystallized. As shown
297 in Figure 3b, mainly the mono-deamidated isoform A₂ (deamidation of Asn⁴⁵) was generated during
298 the crystallogensis. The deamidation of Asn led to the production of a mixture of L-isoAsp, L-Asp,
299 D-isoAsp, and D-Asp residues in the polypeptide chain (Aswad et al., 2000). A lack of electron
300 density was observed in the crystal structure of camel α -La for the loop between β -strands β 2 and β 3
301 that includes Asn⁴⁵ and this could be explained by an heterogeneity in the sample due to spontaneous
302 deamidation in the crystal (Fig. 3b), whereas a clear electron density was observed for the loop
303 between α -helices α 1 and α 2 where Asn¹⁶ is located. Thus, the crystal structure of the camel α -La
304 determined in the present study corresponded to the isoform A₂ with the deamidation of Asn⁴⁵ and no
305 deamidation of Asn¹⁶.

306 In accordance with results of near-UV CD spectra of isoforms A₁ and A₂, the single
307 deamidation had no significant effect on the overall fold of the camel α -La. However, a close
308 structural comparison of the camel α -La with bovine and human α -Las revealed the existence of a
309 small additional α -helix (named α 4) in the camel α -La that included residues 101 to 106. These
310 residues are located in, or close to the flexible loop 105–110 (Chandra et al., 1998; Chrysina et al.,
311 2000) and this could explain that these residues 101–106 were prone to adopt a helical conformation
312 under particular conditions such as deamidation. As described above, the far-UV CD spectra of the
313 isoforms A₁ and A₂ of the camel α -La showed that this protein underwent slightly increase of the α -
314 helix content upon deamidation as confirmed by the increasing 222 nm value. Interestingly, the
315 additional α -helix α 4 was located at the proximity of the Asn⁴⁵ deamidation site in the crystal
316 structure of the camel α -La (Fig. 3a) and such a deamidation process might modify the local
317 physicochemical properties of the protein in the vicinity of the loop β 2- β 3 that includes the
318 deamidation site. Overall, these results suggested that the deamidation of Asn⁴⁵ (isoform A₂) seemed
319 to induce the formation of this additional short α -helix in camel α -La.

320 A DSC approach was used to study the thermostability of the camel α -La upon deamidation
321 (Fig. 4). The DSC thermograms underwent significant shifts as a function of deamidation level (from
322 0 to 2). As the protein was deamidated, it became more heat stable: the melting temperature (T_m)
323 increased significantly ($p < 0.01$) by ca. 3 °C per deamidation level (Table 1). The enthalpy change
324 (ΔH_{cal}) did not differ significantly from an isoform to another, suggesting that same amount of
325 energy was necessary for their unfolding. However, the consequences on the physical features were
326 drastically different, since the native α -La (A₁) precipitated at temperatures higher than 80 °C
327 contrary to the deamidated isoforms (A₂ and A₃) for which the denaturation process was reversible
328 between 20 and 100 °C. Extra negative charges carried by the isoAsp or Asp residues would
329 strengthen the intramolecular electrostatic interactions of the α -La molecule. The conclusions of
330 Atri, Saboury, Moosavi-Movahedi, Kavousi, and Ariaeenejad (2015) substantiate this possible

331 explanation. Indeed, the authors observed that binding of zinc ion onto a secondary site of camel α -
332 La decreases thermal stability, as intramolecular electrostatic interactions weaken. This secondary
333 binding site is identified in human α -La and concerns in particular residues Glu⁴⁹ and Glu¹¹⁶ located
334 on the surface of the molecule (Noyelle & Van Dael, 2002). In our opinion, the addition of negative
335 charges (by deamidation) should have an opposite effect to Zn binding that shields a number of
336 negative charges on the thermostability of camel α -La. Besides, it is noteworthy that the melting
337 temperature (T_m) and enthalpy change (ΔH_{cal}) determined for the mono-deamidated protein A₂ were
338 very close to those of the camel α -La reported by Atri et al. (2010), supporting the hypothesis that
339 the α -La of their study might have deamidated spontaneously.

340 On the other hand, the thermodynamic parameters of native camel α -La A₁ were rather close
341 to those determined for the bovine α -La (Atri et al., 2010). Nevertheless and unlike the native
342 isoform A₁, the thermal denaturation of the bovine protein is reversible between 15 and 100 °C,
343 according to Boye, Alli, and Ismail (1997). The ability of bovine holo- α -La to renature upon cooling
344 is attributed to the absence of aggregation upon thermal treatment. The secondary structure of the
345 bovine α -La is easily altered by heating but can refold to a conformation similar to that of its native
346 state (Boye et al., 1997). This could explain why Felfoul, Lopez, Gaucheron, Attia, and Ayadi (2015)
347 have observed that camel α -La precipitates more easily than bovine α -La upon milk heat treatment
348 mimicking industrial conditions. With a less ordered secondary structure, the native α -La (isoform
349 A₁) was readily prone to precipitate at high temperature, but not the bovine counterpart. It would
350 seem that the deamidation process would prevent aggregation and precipitation of the camel protein
351 at high temperature by inducing a conformational change resulting in a more ordered secondary
352 structure (additional α -helix α_4 in isoform A₂).

353 Due to its compact structure, bovine α -La is known to be resistant to proteolytic enzymes,
354 and especially to thermolysin, a thermostable enzyme (N'Negue et al., 2006). Thus, the impact of
355 deamidation on the susceptibility of camel α -La towards thermolytic activity was studied in the

356 present work. It is reported that the bovine α -La, in its folded state, is highly resistant to thermolysin
357 at temperatures reaching up to at least 44 °C (N'Negue et al., 2006). The enzyme possesses
358 endopeptidase activity and cleaves the peptide bonds of bovine α -La (unfolded) preferentially at the
359 amino-terminal side of the hydrophobic residues Ile, Leu, Phe, Tyr and, to a lesser extent of Val
360 (N'Negue et al., 2006). The bovine α -La is sensitive to thermolysin only in a molten globule state,
361 for which the hydrophobic clusters are more accessible. Indeed, at a temperature of 70 °C, the bovine
362 protein adopts a partly unfolded, reversible state and its hydrolysis is readily achieved by thermolysin
363 (N'Negue et al., 2006). The present work shows that camel α -La was also resistant to thermolysin,
364 similarly to the bovine protein, as few peptides were released after incubation for 3 h at 37 °C (Fig.
365 5). The camel protein was folded in a compact structure conferring this resistance. The nonenzymatic
366 deamidation did not change the behaviour of camel α -La toward the thermolysin, as similar HPLC
367 profiles were obtained between the three isoforms A₁, A₂, and A₃ (Fig. 5). The fact that the
368 deamidated isoforms were equally resistant to thermolysin was expected, because the altered proteins
369 adopted a slightly more ordered secondary structure while keeping the native 3D structure, and also
370 acquired conformations more stable toward heat treatment. The altered isoforms might not expose
371 their hydrophobic clusters to the solvent, so that aggregation and subsequent precipitation upon
372 thermal treatment did not occur, on the contrary to the native isoform, and the sites of hydrolysis by
373 thermolysin were kept hidden in the structure. Salami et al. (2009) reported that the pancreatic
374 enzymes, i.e., trypsin and chymotrypsin, are able to partly degrade camel α -La *in vitro*, the latter
375 being a better substrate than the bovine counterpart, both in the native and molten globule states.
376 Trypsin was also used in the present study (data not shown). As observed with thermolysin, the
377 camel α -La isoforms displayed a relative resistance to trypsin with similar HPLC profiles (i.e. few
378 peptides generated and significant remaining protein).

379 After camel milk or milk-derived food intake, the α -La might undergo a deamidation
380 mechanism in the gut, the physiological conditions, i.e., pH 7.0–8.0, and 37 °C, being favorable for
381 this process to take place. The altered protein would be resistant to pancreatic proteases or brush-

382 border membrane peptidases in the intestinal tract, and might acquire biological activity, for instance
383 against cancer cells, in a way similar to HAMLET (Ho et al., 2017) or camel oleic acid-binding α -La
384 (Atri et al., 2011; Uversky et al., 2017). If case the α -La is hydrolyzed, the generated peptides with
385 an Asn-Gly motif are more readily prone to deamidate, as they lack ordered secondary structure that
386 inhibits the nonenzymatic deamidation in proteins (Robinson & Robinson, 2004). Thus, peptides
387 containing the Asn¹⁶-Gly¹⁷ sequence would be more easily deamidated in the gut, whereas the
388 reaction is limited in the whole protein. This would result in accumulation of unusual residues such
389 as L/D-isoAsp and D-Asp that might either have a deleterious effect in term of food allergy or gain
390 some benefits, for instance in the recognition of integrins overexpressed in the membrane of tumor
391 cells. In this context, it is interesting to note that the motifs isoAsp-Gly-Asn-Arg or Asp-Gly-Asn-
392 Arg at position 45–48 of the camel α -La presents similarities to sequences isoAsp-Gly-Arg
393 (Mastrangeli et al., 2018) and Arg-Gly-Asp (Polo et al., 2018) that bind efficiently to some members
394 of the integrin family, as very recently reported.

395

396 **4. Conclusion**

397

398 The α -La of the *Camelidae* family is the only one that possesses two sites of nonenzymatic
399 deamidation among the known α -Las in other mammals. Devoid of Asn-Gly sequence, the bovine α -
400 La does not deamidate spontaneously and remains chemically stable. The present study focused on
401 the impact of the deamidation on the structure and stability of camel α -La. This post-translational
402 modification reinforced the stability of the protein toward heat treatment and preserved the resistance
403 toward proteolysis. Our experimental findings suggest that the deamidation process is able to induce
404 a conformational change with an extra α -helix in the C-terminal region that conferred higher stability
405 of the protein. To understand the biological significance of this kind of chemical alteration, further
406 investigations on the bioavailability and health impact of the camel α -La need to be performed.
