Abstract

Explicit solutions for a class of linear backward stochastic differential equations (BSDE) driven by Gaussian Volterra processes are given. These processes include the multifractional brownian motion and the multifractional Ornstein-Uhlenbeck process. By an Itô formula, proven in the context of Malliavin calculus, the BSDE is associated to a linear second order partial differential equation with terminal condition whose solution is given by a Feynman-Kac type formula. An application to self-financing trading strategies is discussed.

1 Introduction

A backward stochastic differential equation (BSDE) with a generator $f : [0, T] \times \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$, a terminal value $\xi_T$ and driven by a stochastic process $X = (X^1, ..., X^n)$ is given by the equation

$$Y_t = \xi_T - \int_t^T f(s, Y_s, Z_s)ds + \int_t^T Z_s dX_s, \quad 0 \leq t \leq T.$$  \hspace{1cm} (1)

A solution is a pair of square integrable processes $Y$ and $Z = (Z^1, ..., Z^n)$ that are adapted to the filtration generated by $X$. Such equations appear especially in the context of asset pricing and hedging theory in finance and in the context of stochastic control problems. BSDEs may be considered as an alternative to the more familiar partial differential equations (PDE) since the solutions of BSDEs are closely related to classical or viscosity solutions of associated PDEs. As a consequence, BSDEs may be used for the numerical solution of nonlinear PDEs.

BSDEs driven by brownian motion have been studied extensively after the first general existence and uniqueness result proved by E. Pardoux and S.G. Peng [17]. For a synthesis of this research work we may refer to the recent textbooks [6], [8], [16], [18], [21], [24]. More recently BSDEs driven by fractional brownian motions have been investigated (see, e.g., [2], [12], [11], [13], [14], [20], [22].

∗Laboratoire de Mathématiques: Modélisation Déterministe et Aléatoire, Hammam Sousse, Tunisie et UMR-CNRS 7502, Institut Élie Cartan de Lorraine, Nancy, France

Since fractional brownian motions (with Hurst index \( H \in (0, 1/2) \cup (1/2, 1) \)) are neither martingales nor Markov processes, new methods have been developed to show the wellposedness of BSDEs in certain function spaces. Hereby the stochastic integral \( \int_0^T Z_s dX_s \) has frequently been defined as a Skorohod integral in the framework of Malliavin calculus, and the notion of quasi-conditional expectation has been introduced, since the classical notion of conditional expectation seems not to be convenient for a proof of the existence and uniqueness of solutions to BSDEs whose driving process is not a martingale ([15], Lemma 1.2.5). Very few articles are concerned with BSDEs for more general gaussian processes ([3], [4]) or in the context of the theory of rough paths [9]. In [3] the stochastic integral \( \int_0^T Z_s dX_s \) is understood in the Wick-Itô sense, and the existence and uniqueness of the solution of (1) is proved for a class of gaussian processes which includes fractional Brownian motion. The proof is based on a transfer theorem that aims to reduce the question of wellposedness to BSDEs driven by brownian motion. In [4] it is shown that the wellposedness of linear BSDEs with general square integrable terminal condition \( \xi \) holds true if and only if \( X \) is a martingale.

This paper is concerned with linear BSDEs driven by gaussian Volterra processes \( X \). This class of processes contains multifractional brownian motions and multifractional Ornstein-Uhlenbeck processes. Contrary to fractional Brownian motion where the Hurst parameter \( H \) is constant, it becomes for multifractional Brownian motion a function \( h \) which is assumed here to be differentiable and with values in \((1/2, 1)\). The aim is to obtain the solution of the linear BSDE with the associated linear PDE whose classical solution is given explicitly. This generalizes a result in [2] obtained for fractional brownian motion. We define the stochastic integral \( \int_0^T Z_s dX_s \) as a divergence integral, and extend an Itô formula in [1] to the multidimensional case. The Itô formula is then applied to the solution of the associated PDE in order to get a solution of the BSDE. The question of uniqueness of solutions of (not necessarily linear) BSDEs driven by Volterra processes will be treated in a separate paper. Special attention is given to the fact that the variance of Volterra processes is not necessarily an increasing function of time, but in general only of bounded variation. The explicit solution of the associated PDE contains this variance and is given by a Feynman-Kac type formula on time intervals where it is increasing. The application of this formula to the BSDEs is therefore restricted to time intervals where this variance is increasing.

In this section we define the class of Volterra processes \( X \) we have in mind and the linear BSDEs and the associated PDE. Section 2 is concerned with complements on the Skorohod integral with respect to Volterra processes. The Itô formula is proved in Section 3 and applied in Section 4 to the linear BSDE.

1.1 Gaussian Volterra processes

Let \( X = \{ X_t, 0 \leq t \leq T \} \) be a zero mean continuous Gaussian process given by

\[
X_t = \int_0^T K(t, s) dW_s
\]

(2)

where \( W = \{ W_t, 0 \leq t \leq T \} \) is a standard Brownian motion and \( K : [0, T]^2 \to \mathbb{R} \) is a square integrable kernel, i.e. \( \int_{[0,T]^2} K(t, s)^2 dt ds < +\infty \). We assume that \( K \) is of Volterra type, i.e. \( K(t, s) = 0 \) whenever \( t < s \). Usually, the representation (2) is called a Volterra representation of \( X \). Gaussian Volterra processes and their stochastic analysis have been studied e.g. in [1], [7] and [19]. In [1] \( K \) is called regular if it satisfies

\((H)\) For all \( s \in (0, T), \int_0^T |K| ((s, T], s)^2 ds < \infty \), where \( |K| ((s, T], s) \) denotes the total variation of \( K(., s) \) on \((s, T] \).
We assume the following condition on \( K(t, s) \) which is more restrictive than (H) ([1], [7]):

(H1) \( K(t, s) \) is continuously differentiable in the variable \( t \) in \( 0 < s < t < T \).

(H2) For some \( 0 < \alpha, \beta < \frac{1}{2} \), there is a finite constant \( c > 0 \) such that, for all \( s > 0 \),
\[
|\frac{\partial K}{\partial t}(t, s)| \lesssim c(t-s)^{\alpha-1} \left( \frac{t}{s} \right)^{\beta}, \quad t \in (s, T].
\]

The covariance function of \( X \) is given by
\[
R(t, s) := \mathbb{E}X_tX_s = \int_0^{\inf(t, s)} K(t, u)K(s, u)du. \tag{3}
\]

We discuss shortly some examples of Gaussian Volterra processes that satisfy (H1) and (H2).

Example 1. The multi-fractional brownian motion (mbm) \( (B^{h(t)}_t, 0 \leq t \leq T) \) with Hurst function \( h : [0, T] \to [\alpha, b] \subset (\frac{1}{2}, 1) \). Its kernel is given by [5]
\[
K(t, s) = s^{1/2-h(t)} \int_s^t (y-s)^{h(t)-3/2}y^{h(t)-1/2}dy, \tag{4}
\]
where \( h \) is assumed to be continuously differentiable with bounded derivative. We get
\[
\frac{\partial K}{\partial t}(t, s) = h'(t)s^{-h(t)}\int_s^t (y-s)^{h(t)-\frac{3}{2}}y^{h(t)-\frac{1}{2}}\ln \left( \frac{y}{s} - 1 \right)ydy + s^{\frac{1}{2}-h(t)}(t-s)^{h(t)-\frac{1}{2}}t^{h(t)-\frac{3}{2}}.
\]

A straightforward calculation shows that (H2) is satisfied with \( \alpha = a - \frac{1}{2}, \beta = b + \epsilon - \frac{1}{2} \) with \( \epsilon \) small enough and \( c \) depends on \( a, b, T \) and \( \epsilon \). The mbm generalizes fractional brownian motion (fbm) with Hurst index \( H > 1/2 \). Mbms are a more flexible model than fbms since the Hölder continuity of its trajectories varies with \( h \). The trajectories of mbm \( B^{h(t)}_t \) are in fact locally Hölder continous of order \( h(t) \) at \( t \).

Example 2. The multi-fractional Ornstein-Uhlenbeck process \( U = \{U_t, 0 \leq t \leq T\} \) given by
\[
U_t = \int_0^t e^{-\theta(t-s)}dB^{h(s)}_s,
\]
where \( \theta > 0 \) is a parameter and \( B^h \) is the mbm of Example 1. The kernel of \( U \) is given by
\[
K_t(r) = \int_r^t e^{-\theta(t-s)}\frac{\partial K}{\partial s}(s, r)ds = K(t, r) - \theta \int_r^t e^{-\theta(t-s)}K(s, r)ds.
\]

In fact we have
\[
\int_0^t K(t, r)dW_r = \int_0^t K(t, r)dW_r - \theta \int_0^t \left( \int_r^t e^{-\theta(t-s)}K(s, r)ds \right) dW_r = B^{h(t)}_t - \theta \int_0^t e^{-\theta(t-s)}B^{h(s)}_s ds.
\]

An integration by parts gives the representation of \( U \). We notice that in the framework of the divergence integral (Section 2) the integral with respect to mbm can be reduced to an integral with respect to brownian motion. (H2) is satisfied with the same values of \( \alpha \) and \( \beta \) as in Example 1.

Example 3. The Liouville multi-fractional Brownian motion (LmBm) \( (B^{L, h(t)}_t, t \in [0, T]) \) with Hurst function \( h \) as in Example 1. Its kernel is given by \( \tilde{K}(t, r) = (t-r)^{h(t)-\frac{1}{2}}1_{(0, t)}(r) \).
1.2 Linear backward stochastic differential equations

Let \( W = (W^1, \ldots, W^n) \) a standard brownian motion in \( \mathbb{R}^n \), defined on the probability space \((\Omega, \mathcal{F}, P)\), and let \( \mathbb{F} = \{ \mathcal{F}_t \subset \mathcal{F}, t \in [0,T]\} \) be the filtration generated by \( W \) and augmented by the \( P \)-null sets. We consider the \( \mathbb{R}^n \)-valued Volterra processes \( X = (X^1, \ldots, X^n) \) given by

\[
X^j_t = \int_0^t K^j(t,s)dW^j_s, \quad j = 1, \ldots, n,
\]  

(5)

where \( K^j : [0,T]^2 \rightarrow \mathbb{R} \) satisfies the conditions \((H1)\) and \((H2)\). Let \( \sigma^j, j = 1, \ldots, n \) be bounded functions on \([0,T]\), and let \( b^j \in \mathcal{C}^1((0,T), \mathbb{R}) \cap \mathcal{C}([0,T], \mathbb{R}), j = 1, \ldots, n \). The process \( N := (N^1, \ldots, N^n) \) is defined by

\[
N^j_t = b^j_t + \int_0^t \sigma^j_u dX^j_u, \quad t \in [0,T].
\]  

(6)

Let \( t_0 \geq 0 \) be fixed, and denote by \( L^2(\mathbb{F}, \mathbb{R}^n) \) the set of \( \mathbb{F} \)-adapted \( \mathbb{R}^n \)-valued processes \( Z \) such that \( \mathbb{E}(\int_0^T |Z_t|^2 \, dt) < \infty \). We consider the linear BDSE for the processes \( Y_t = (Y_t, t \in [t_0,T]) \in L^2(\mathbb{F}, \mathbb{R}) \) and \( Z = ((Z^1_t, \ldots, Z^n_t), t \in [t_0,T]) \in L^2(\mathbb{F}, \mathbb{R}^n) \) given by

\[
Y_t = g(N_T) - \int_t^T [f(s) + A_1(s)Y_s - A_2(s)Z_s]ds + \int_t^T Z_s \delta X_s, \quad t \in [t_0,T],
\]  

(7)

where the real-valued functions \( g, f, A_1 \) and the \( \mathbb{R}^n \)-valued function \( A_2 \) are supposed to be known and the integral \( \int_t^T Z_s \delta X_s \) is defined as a divergence integral and will be studied in Sections 2 and 3. \( (7) \) is associated to the following second order linear PDE with terminal condition

\[
\frac{\partial u}{\partial t}(t, x) = -\frac{1}{2} \sum_{j=1}^n \frac{d}{dt} \text{Var}(N^j_t) \frac{\partial^2 u}{\partial x_j^2}(t, x) + \sum_{j=1}^n \sigma^j_t A^j_2(t) - \frac{d}{dt} b^j_t \frac{\partial u}{\partial x_j}(t, x) + A_1(t)u(t, x) + f(t),
\]  

\[
u(T, x) = g(x), \quad (t, x) \in [t_0, T] \times \mathbb{R}^n.
\]  

(8)

By means of the Itô formula of Section 3 we show that

\[
Y_t := u(t, N_t) \quad \text{and} \quad Z^j_t := -\sigma^j_t \frac{\partial u}{\partial x_j}(t, N_t), \quad j = 1, \ldots, n
\]  

(9)

is a solution of \((7), (8)\) is solved explicitly in Section 4.

A possible application of this result is to formulate and to solve, in the context of Volterra processes, the well known problem of self-financing trading strategies against a positive contingency claim \( \xi \) at a time \( T \). Volterra processes are in fact more flexible than brownian motion to modelize the different kinds of uncertainties that occur on financial markets. Let \( P^0_t \) be the price at time \( t \in [t_0, T] \) of a riskless asset that is governed by the equation \( dP^0_t = P^0_{t-r}dt, \) \( r \) is the short rate, and let \( P^j_t, j = 1, \ldots, n \) be the prices of \( n \) risky assets that are governed by the equations \( dP^j_t = P^j_{t-r}dt + \sigma^j_t \delta X^j_u \), where \( b^j_t \) is the appreciation rate and \( \sigma^j_t \) is the volatility. Then \( \theta^j_t := (b^j_t - r) / \sigma^j_t \) is called the risk premium for the risky asset \( j \). The problem is to find the part \( \pi^j_t \) of the wealth \( V_t \) to invest at time \( t \) in the asset \( j \), \( j = 1, \ldots, n \). Of course this decision can only be based on the current information \( \mathcal{F}_t \), i.e. the processes \( \pi^j_t \) and \( \pi^0_t := V_t - \sum_{j=1}^n \pi^j_t \) must be \( \mathcal{F}_t \)-adapted. In the model of Harrison and Pliska ([10]) \( V_t \) satisfies the equation \( dV_t = r_t V_t dt + \sum_{j=1}^n (b^j_t - r_t) \pi^j_t dt + \sum_{j=1}^n \pi^j_t \sigma^j_t dX^j_t \) with final condition \( V_T = \xi \). If \( \xi \) is of the form \( g(N_T), (V_t, \pi^1_t, \ldots, \pi^n_t), t \in [t_0, T], \) is the solution of \((7)\) with \( A_1(s) = r_s, \) and \( A^j_2(s) = \theta^j_s \sigma^j_s, \) \( j = 1, \ldots, n.\)
2 On the divergence integral for Gaussian Volterra processes

The kernel $K$ in (2) defines a linear operator in $L^2([0, T])$ given by $(K \sigma)_t = \int_0^t K(t, s) \sigma(s) ds, \sigma \in L^2([0, T])$. Let $E$ be the set of step functions of $[0, T]$, and let $K^*_T : E \to L^2([0, T])$ be defined by

$$(K^*_T \sigma)_u := \int_u^T \sigma_s \frac{\partial K}{\partial s}(s, u) ds.$$

The operator $K^*_T$ is the adjoint of $K$ ([11, Lemma 1]).

Remarks: a) For $s > t$, we have $(K^*_T \sigma 1_{[0, t]})_s = 0$, and we will denote $(K^*_T \sigma 1_{[0, t]})_s$ by $(K^*_T \sigma)_s$ where $K^*_T$ is the adjoint of the operator $K$ in the interval $[0, t]$.

b) If $K(u, u) = 0$ for all $u \in [0, T]$, $(K^*_T 1_{[0, t]})_u = K(r, u)$ for $u < r$. Indeed, if $u < r$, we have

$$(K^*_T 1_{[0, t]})_u = \int_u^T 1_{[0, r]}(s) \frac{\partial K}{\partial s}(s, u) ds = \int_u^r \frac{\partial K}{\partial s}(s, u) ds.$$

Therefore

$$R(t, s) = E[X_t X_s] = \int_0^{\infty} (K^*_T 1_{[0, t]})_u (K^*_T 1_{[0, s]})_u du$$

$$= <K^*_T 1_{[0, t]}, K^*_T 1_{[0, s]} >_{L^2([0, T])}.$$

For $\sigma, \bar{\sigma} \in E$ this may be extended to

$$X(\sigma) := \int_0^t (K^*_T \sigma)_s dW_s \text{ and } E[X(\sigma)X(\bar{\sigma})] = <K^*_T \sigma, K^*_T \bar{\sigma} >_{L^2([0, T])}.$$

Let $H$ be the closure of the linear span of the indicator functions $1_{[0, t]}, t \in [0, T]$ with respect to the scalar product

$$<1_{[0, t]}, 1_{[0, s]} >_H := <K^*_T 1_{[0, t]}, K^*_T 1_{[0, s]} >_{L^2([0, T])}.$$

The operator $K^*_T$ is an isometry between $H$ and a closed subspace of $L^2([0, T])$, and $\| \cdot \|_H$ is a semi-norm on $H$. Furthermore, for $\varphi, \psi \in H$,

$$<K^*_T \varphi, K^*_T \psi >_{L^2([0, T])} = \int_0^T \int_0^T \left( \int_0^{\infty} \frac{\partial K}{\partial r}(r, t) \frac{\partial K}{\partial s}(s, t) dt \right) \varphi(r) \psi(s) ds dr.$$

For further use let

$$\phi(r, s) := \int_0^{\infty} \frac{\partial K}{\partial r}(r, t) \frac{\partial K}{\partial s}(s, t) dt, r \neq s,$$

$$\tilde{\phi}(r, s) := \int_0^{\infty} \left| \frac{\partial K}{\partial r}(r, t) \right| \left| \frac{\partial K}{\partial s}(s, t) \right| dt, r \neq s.$$

Note that $\phi(r, s) = \partial^2 / \partial s \partial r R(r, s) (r \neq s)$ ($\phi$ may be infinite on the diagonal $r = s$). Let $|H|$ be the closure of the linear span of indicator functions with respect to the semi-norm given by
\[ \| \varphi \|_{\mathcal{H}}^2 = \int_0^T \left( \int_t^T |\varphi_r| |\partial K/\partial r| (r, t) \right)^2 dt \]
\[ = 2 \int_0^T dr \int_0^dr \int_0^d s \phi(r, s) |\varphi_r||\varphi_s|. \]

We briefly recall some basic elements of the stochastic calculus of variations with respect to \( X \). We refer to [15] for a more complete presentation. Let \( S \) be the set of random variables of the form \( F = f(X(\varphi_1), \ldots, X(\varphi_n)) \), where \( n \geq 1 \), \( f \in C_0^\infty(\mathbb{R}^n) \) (\( f \) and its derivatives are bounded) and \( \varphi_1, \ldots, \varphi_n \in \mathcal{H} \). The derivative of \( F \)
\[ D^X F := \sum_{j=1}^n \frac{\partial f}{\partial x_j}(X(\varphi_1), \ldots, X(\varphi_n))\varphi_j. \]

is an \( \mathcal{H} \)-valued random variable, and \( D^X \) is a closable operator from \( L^p(\Omega) \) to \( L^p(\Omega; \mathcal{H}) \) for all \( p \geq 1 \). We denote by \( \mathcal{D}^X_{1,2} \) the closure of \( S \) with respect to the semi-norm
\[ ||F||^p_{1,2} = E|F|^p + E\|D^X F\|_{\mathcal{H}}^p. \]

Let \( \delta^X \) the adjoint of \( D^X \). For \( u \in L^2(\Omega; \mathcal{H}) \) in the domain of \( \delta^X \), \( \delta^X(u) \) is the element in \( L^2(\Omega) \) defined by the duality relationship
\[ E\left[ F\delta^X(u) \right] = E\left[ <D^X F, u, >_{\mathcal{H}} \right], \quad F \in \mathcal{D}^X_{1,2}. \]

We also use the notation \( \int_0^T u_t \delta X_t \) for \( \delta^X(u) \). A class of processes that belong to the domain of \( \delta^X \) is given as follows: let \( \mathcal{S}^H \) be the class of \( \mathcal{H} \)-valued random variables \( u = \sum_{j=1}^n F_j h_j \) (\( F_j \in \mathcal{S} \), \( h_j \in \mathcal{H} \)), and let, for \( p \geq 1 \), \( \mathcal{D}^X_{1,p}(\mathcal{H}) \) be the completion of \( \mathcal{S}^H \) with respect to the semi-norm
\[ ||u||^p_{1,p,\mathcal{H}} = E|u|^p_{\mathcal{H}} + E\|D^X u\|_{\mathcal{H}^{\mathcal{H}}}^p. \]

Here \( \| \cdot \|_{\mathcal{H}^{\mathcal{H}}} \) is given by
\[ \langle D^X u, D^X v \rangle_{\mathcal{H}^{\mathcal{H}}} = \int_{[0,T]^4} D^X_s u_t D^X_t v_s \tilde{\phi}(s, s') \tilde{\phi}(t, t') dsdt ds'dt'. \]

In the same way \( \mathcal{D}^X_{1,p}(\mathcal{H}) \) is defined as the completion of \( \mathcal{S}^{\mathcal{H}} \) under the semi-norm \( ||u||^p_{1,p,\mathcal{H}} \) where
\[ ||D^X u||^2_{\mathcal{H}^{\mathcal{H}}} = \int_{[0,T]^4} |D^X_s u_t| |D^X_t u_s| |\tilde{\phi}(s, s')\tilde{\phi}(t, t')| dsdt ds'dt'. \]

For \( F \in \mathcal{S} \) let
\[ \mathcal{D}^X_{2} F := \int_0^T \phi(s, t) D^X_t F dt, \quad s \in [0, T]. \]

Then
\[ \langle D^X u, D^X v \rangle_{\mathcal{H}^{\mathcal{H}}} = \int_{[0,T]^2} \mathcal{D}^X_s u_t \mathcal{D}^X_t v_s dsdt. \]
Proposition 2.1. Let \( f,g \in D_{1,2}^X(\mathcal{H}) \). Then the integrals \( \delta^X(f) \) and \( \delta^X(g) \) exist in \( L^2(\Omega) \) and

\[
\mathbb{E}
\left[
\delta^X(f)\delta^X(g)
\right] = \mathbb{E}\langle f,g \rangle_{\mathcal{H}} + \int_0^T ds \int_0^T dt \mathbb{E}
\left[
D^X_s f,D^X_s g
\right].
\] (10)

Remark. With the choice \( f = g \), Proposition 2.1 implies \( D_{1,2}^X(\mathcal{H}) \subset \text{dom}(\delta^X) \). In fact, for \( f \in D_{1,2}^X(\mathcal{H}) \),

\[
|f|_{\mathcal{H}} \leq \|f\|_{\mathcal{H}} \quad \text{and} \quad \int_{[0,T]^2} D^X_s f D^X_s g dsdt \leq \|D^X f\|_{\mathcal{H}[\otimes]_{\mathcal{H}}}.
\]

For the proof we need the following lemma.

Lemma 2.2. Let \( G \in D_{1,2}^X \) and \( f \in \text{dom}(\delta^X) \). Then

\[
\mathbb{E}
\left[
\delta^X(f)G
\right] = \int_0^T \mathbb{E}
\left[
D^X_t G
\right] dt.
\]

Proof of the Lemma.

\[
\mathbb{E}
\left[
\delta^X(f)G
\right] = \mathbb{E}
\left[
< D^X_G(f), >_{\mathcal{H}}
\right] = \mathbb{E}
\left[
< (K_t^*,D^X_G), (K^*f), >_{L^2([0,T])}
\right]
\]

\[
= \mathbb{E}
\left[
\int_0^T dt \int_t^T du_1 f_{u_1} \frac{\partial K}{\partial u_1}(u_1,t) \int_t^T du_2 D^X_{u_2} G \frac{\partial K}{\partial u_2}(u_2,t)
\right]
\]

\[
= \mathbb{E}
\left[
\int_0^T du_1 f_{u_1} \int_0^T du_2 D^X_{u_2} G (u_1,u_2)
\right] = \mathbb{E}
\left[
\int_0^T f_{u_1} D^X_{u_1} G du_1
\right].
\] ■

Proof of Proposition 2.1. Let first \( f,g \in S^{|\mathcal{H}|} \). If \( f = \sum_{j=1}^n h_j \), \( h_j \in \mathcal{H} \), \( j \in [1,n] \), lemma 2.2 in [15] shows that

\[
\delta^X(f) = \sum_{j=1}^n (f_j X(h_j) - \langle D^X f_j,h_j \rangle_{\mathcal{H}}) \in S^{|\mathcal{H}|}.
\]

A straightforward calculation shows \( D^X \delta^X(f) \in S^{|\mathcal{H}|} \) and \( \delta^X(D^X f) \in S^{|\mathcal{H}|} \). Moreover, by means of the notion of directional derivatives ([15], p.27), one shows

\[
\langle f, D^X(\delta^X(g)) \rangle_{\mathcal{H}} = \langle f, \delta^X(D^X g) + g \rangle_{\mathcal{H}}.
\]

Therefore

\[
\mathbb{E}
\left[
\delta^X(f)\delta^X(g)
\right] = \mathbb{E}\langle f, D^X(\delta^X(g)) \rangle_{\mathcal{H}} = \mathbb{E}\langle f, g \rangle_{\mathcal{H}} + \mathbb{E}\langle f, \delta^X(D^X g) \rangle_{\mathcal{H}}.
\]

Moreover

\[
\mathbb{E}\langle f, \delta^X(D^X g) \rangle_{\mathcal{H}} = \mathbb{E}
\left[
\int_0^T (K^*_t f)_u (K^*_t \delta^X(D^X g))_u du
\right]
\]

\[
= \mathbb{E}
\left[
\int_0^T du \int_0^T ds \frac{\partial K}{\partial s}(s,u) \int_u^T dr \delta^X(D^X g) \frac{\partial K}{\partial r}(r,u)
\right]
\].
This implies $\partial/\partial t F$ and the same property holds for $F$. Let now $f \in L^3(\mathcal{H})$. Itô formula proposition 1.3.6 in [15] the limit is $F$.

Let now $f \in D_{\mathcal{X}_t}^n(\mathcal{H}_t)$. There exists a sequence $(f_n)_{n \in \mathbb{N}} \subset S^{|\mathcal{H}|}$ such that, as $n \to \infty$, $f_n \to f$ in $L^2(\Omega, \mathcal{H})$ and $D^X f_n \to D^X f$ in $L^2(\Omega, \mathcal{H} \otimes \mathcal{H})$. Therefore $\delta X(f_n)$ converges in $L^2(\Omega)$. By proposition 1.3.6 in [15] the limit is $\delta X(f)$.

$\hfill \blacksquare$

### 3 Itô formula

Let $F \in C^{1,2}([0, T] \times \mathbb{R}^n)$ and suppose that

$$
\max \left( |F(t, x)|, \left| \frac{\partial F}{\partial t}(t, x) \right|, \left| \frac{\partial F}{\partial x_j}(t, x) \right|, \left| \frac{\partial^2 F}{\partial x_i \partial x_j}(t, x) \right|, j = 1, \ldots, n \right) \leq c e^{\lambda |x|^2},
$$

for all $t \in [0, T]$ and $x \in \mathbb{R}^n$, where $c, \lambda$ are positive constants such that $\lambda < \frac{1}{4} \min_i (\sup_{t \in [0, T]} Var(N_i))^{-1}$.

This implies

$$
\mathbb{E} \left| F(t, N_t) \right|^2 \leq c^2 \mathbb{E} e^{2\lambda |N_t|^2}
= \frac{c^2}{(2\pi)^{n/2}} \prod_{i=1}^n \frac{1}{Var(N_i)^{1/2}} \int \exp \left( 2\lambda x_i^2 - \frac{1}{2} \frac{x_i^2}{Var(N_i)} \right) dx_i < \infty,
$$

and the same property holds for $\partial/\partial t F(t, x), \partial/\partial x_j F(t, x)$ and $\partial^2/\partial x_i \partial x_j F(t, x), j = 1, \ldots, n$.

**Theorem 3.1.** Let $N$ be given by (6), and suppose that, for $j = 1, \ldots, n$, the kernels $K^j$ of $X^j$ satisfy (H1) and (H2), $b^j \in C^1((0, T], \mathbb{R}) \cap C([0, T], \mathbb{R})$, and $\sigma = \{\sigma^j_t, t \in [0, T], j = 1, \ldots, n\}$ is bounded. If $F \in C^{1,2}([0, T] \times \mathbb{R}^n)$ satisfies (11), $\partial/\partial x_j F(\cdot, N_t) \in D_{\mathcal{X}_t}^n(\mathcal{H}_t)$, $j = 1, \ldots, n$ and, for all $t \in [0, T]$,

$$
F(t, N_t) = F(0, 0) + \int_0^t \frac{\partial F}{\partial s}(s, N_s) ds + \sum_{j=1}^n \int_0^t \frac{\partial F}{\partial x_j}(s, N_s) \left( \frac{d}{ds} b^j_t ds + \sigma^j_t \delta X^j_s \right)
$$
should be replaced by the derivatives of the covariances of \( \tilde{N} \) that the matrix \( \tilde{\sigma} \) solution of the BSDE (7) with \( u \) for an application to the solution \( R \) of (6). We notice that this model is too restrictive (see also the remark below). For this reason we prefer to consider BSDEs with perturbation \( X \), defined on \( \mathbb{R}^n \) only, i.e. if \( F \) and its derivatives are bounded, a hypothesis that is in general too restrictive for an application to the solution \( u \) of the PDE (8). The second problem is that, in order to get the solution of the BSDE (7) with \( \tilde{N} \), the derivatives of the variances of \( N \) and the second order term of (8) should be replaced by the derivatives of the covariances of \( \tilde{N} \), and it would be necessary to assume that the matrix \( \frac{\partial}{\partial s} \text{Cov}(\tilde{N}_i^j, \tilde{N}_j^i) \) is positive definite, a hypothesis which seems to be restrictive (see also the remark below). For this reason we prefer to consider BSDEs with \( N \) given by (6). We notice that

\[
\text{Var}(N_i^j) = E \left( \int_0^t \left( K_t^{\ast,i} \sigma_t^j \right)^2 ds \right)^2, \quad \text{and} \quad \frac{d}{dt} \text{Var}(N_i^j) = 2 \sigma_t^i \mathbb{E}[W_s^j, N_i^j],
\]

b) In the model where \( \tilde{\sigma} \) is diagonal, \( X^i \) and \( X^j \) are defined with independent brownian motions \( W^i \) and \( W^j \) if \( i \neq j \). This differs from the model where all the Volterra processes \( \mathcal{X}^j \) are defined with the same brownian motion \( \mathcal{W} \) as follows:

\[
\tilde{\mathcal{X}}_t^j = \int_0^t K^j(t,s) \delta W_s, \quad \tilde{N}_t^j = b_t^j + \int_0^t \sigma_t^j \delta \mathcal{X}_s^j, \quad t \in [0,T], \quad j = 1, \ldots, n.
\]

In this case the processes \( \tilde{N}^j \) are correlated, and the matrix \( \frac{d}{dt} \text{Cov}(\tilde{N}_i^j, \tilde{N}_j^i) \) is not diagonal. For \( n = 2 \) a direct verification shows that this matrix is negative (semi-)definite.

Proof of Theorem 3.1

1. Let us first show that \( \partial / \partial x_j F(\cdot, N) \in \delta X^j \) for all \( j = 1, \ldots, n \). For this we show that \( \partial / \partial x_j F(\cdot, N) \in \delta X^j \) for all \( j = 1, \ldots, n \) and the process \( X \) is independent of \( N \).
\(D_{X_j}^i (\mathcal{H}^j)\), where \(\mathcal{H}^j\) is the space defined in Section 2 with \(X\) replaced by \(X^j\). The terms \(\phi^j\) and
\(\hat{\phi}^j\) refer now to the kernel \(K^j\) of \(X^j\). The constants in the inequalities below may vary from line to line.

\[
E \left\| \frac{\partial F}{\partial x_j} (\cdot, N) \right\|_{\mathcal{H}^j}^2 \leq cE \int_0^T \left( \int_s^T \left| \frac{\partial F}{\partial x_j} (t, N_t) \right| \, dt \right) \, ds \leq cE \int_0^T \left( \int_s^T \exp(\lambda \, |N_t|^2) (t-s)^{\alpha-1} \left( \frac{t-s}{s} \right)^{\beta} \, dt \right) \, ds
\]

Applying Hölder’s inequality to \(1 < p < \frac{1}{\alpha} < 2\) and \(q\) its conjugate, we get

\[
\left( \int_s^T \exp(\lambda \, |N_t|^2) (t-s)^{\alpha-1} \left( \frac{t-s}{s} \right)^{\beta} \, dt \right)^{\frac{1}{p}} \leq \left( \int_s^T \exp(q \lambda \, |N_t|^2) (t-s)^{\beta} \, dt \right)^{\frac{1}{q}} \left( \int_s^T (t-s)^{p\alpha-1} \left( \frac{t-s}{s} \right)^{\beta} \, dt \right)^{\frac{1}{p}}.
\]

Then

\[
E \left( \int_0^T \exp(q \lambda \, |N_t|^2) (t-s)^{\alpha-1} \left( \frac{t-s}{s} \right)^{\beta} \, dt \right) \leq E \left( \int_0^T \exp(q \lambda \sup_{t \in [0,T]} |N_t|^2) (t-s)^{\beta} \, dt \right) \leq \frac{1}{q} \prod_{i=1}^n E \exp(2 \lambda \sup_{t \in [0,T]} |N_i|^2) dt < \infty
\]

for \(\lambda < \frac{1}{q} \min(\sup \, \text{Var}(N_i))^{-1}\). Moreover,

\[
\int_0^T \left( \int_s^T (t-s)^{p\alpha-1} \left( \frac{t-s}{s} \right)^{\beta} \, dt \right)^{\frac{1}{p}} \, ds \leq T^{2(\alpha-1)+\frac{2}{p}} \beta(1-2\beta, 2(\alpha-1)+\frac{2}{p} + 1).
\]

It remains to show that

\[
E \left\| D_{X_j}^i \frac{\partial F}{\partial x_j} (\cdot, N) \right\|_{\mathcal{H}^j \otimes \mathcal{H}^j}^2 < \infty.
\]

By (11),

\[
E \left( \frac{\partial^2 F}{\partial x_j^2} (t, N_t) \right)^2 \leq cE \exp(2 \lambda \, |N_t|^2) \leq cE \prod_{i=1}^n (1 + 4\lambda \text{Var}(N_i))\lambda^{-1/2},
\]

and by the choice of \(\lambda\) the right side stays bounded in \(t \in [0,T]\). The finiteness of the remaining integrals follows from \((H1), (H2)\) applied to \(K^j\).

2. We proceed now to the outline of the proof of the Itô formula. Let

\[
N_i^{t+} = b_i^t + \int_0^t \left( \int_s^t \sigma_i^s \frac{\partial K_j}{\partial r} (r+\epsilon, s) \, dr \right) \, dW_r \quad t \leq T - \epsilon.
\]
Then, $F(t, N^1_t, ..., N^n_t)$ has locally bounded variation, and we can write

$$dF(t, N^1_t, ..., N^n_t) = \frac{\partial F}{\partial t}(t, N^1_t, ..., N^n_t)dt + \sum_{i=1}^{n} \frac{\partial F}{\partial x_i}(t, N^1_t, ..., N^n_t)dN^i_t$$

$$= \left(\frac{\partial F}{\partial t}(t, N^1_t) + \sum_{j=1}^{n} \frac{\partial F}{\partial x_j}(t, N^1_t) \frac{d}{dt}b^j_t\right) dt + \sum_{j=1}^{n} \frac{\partial F}{\partial (t, N^1_t)} \frac{\partial K^j}{\partial t}(t, t, s, \delta W^j_s) dt$$

with the notation $N^\varepsilon = (N^1_t, ..., N^n_t)$. Furthermore,

$$\frac{\partial F}{\partial x_j}(t, N^1_t) \frac{\partial K^j}{\partial t}(t, t, s, \delta W^j_s) = \sigma^j_t \left[ \int_0^t \frac{\partial F}{\partial x_j}(t, N^1_t) \frac{\partial K^j}{\partial t}(t, t, s, \delta W^j_s) ds + \int_0^t D_s^{W^j} \left( \frac{\partial F}{\partial x_j}(t, N^1_t) \right) \frac{\partial K^j}{\partial t}(t, t, s, \delta W^j_s) ds \right],$$

where

$$D_s^{W^j} \left( \frac{\partial F}{\partial x_j}(t, N^1_t) \right) = \frac{\partial^2 F}{\partial x_j^2}(t, N^1_t)D_s^{W^j} N^j_t = \frac{\partial^2 F}{\partial x_j^2}(t, N^1_t) \int_s^t \sigma^j_t \frac{\partial K^j}{\partial r}(r, t, s, \delta W^j_s) dr.$$ 

Therefore

$$F(t, N^1_t) = F(0, 0) + \int_0^t \left( \frac{\partial F}{\partial s}(s, N^1_s) + \sum_{j=1}^{n} \frac{\partial F}{\partial x_j}(s, N^1_s) \frac{d}{ds}b^j_s \right) ds$$

$$+ \sum_{j=1}^{n} \int_0^t \left( \int_s^t \sigma^j_t \frac{\partial F}{\partial x_j}(r, N^1_r) \frac{\partial K^j}{\partial r}(r, t, s, \delta W^j_s) dr \right) \delta W^j_s$$

$$+ \frac{1}{2} \sum_{j=1}^{n} \int_0^t \left( \int_s^t \frac{\partial^2 F}{\partial x_j^2}(r, N^1_r) \frac{\partial K^j}{\partial r}(r, t, s, \delta W^j_s) \right) \left( \int_0^t \left( K^j_{r,s} \sigma^j_s \right)^2 ds \right) dr.$$ 

We notice that the divergence integral in the second line above appears now outside of the integral with respect to $dr$. This permutation may be shown with the definition by duality of the divergence integral. The integral coincides, up to $\varepsilon$, with the divergence integral that appears in the statement of the theorem. The last term coincides, up to $\varepsilon$, with the term in Remark a) after the theorem. It remains to show that the terms above converge in $L^2(\Omega)$ towards the terms in the statement of the theorem as $\varepsilon \to 0$. This can be done for each integral similarly as in the proof of theorem 4 in [1].

4 Solvability of linear BSDEs

As mentioned in the introduction the aim is to apply the Itô formula (12) to the classical solution $u$ of the PDE (8) and to show that $Y$ and $Z$ defined by (9) satisfy the BSDE (7). We will show later in this section that $u$ in fact satisfies the growth condition (11) under a suitable growth condition on the final condition in (7).

The Itô formula (12), applied to $u$ reads

$$u(t, N_t) = u(T, N_T) - \int_t^T \frac{\partial u}{\partial s}(s, N_s) ds - \sum_{j=1}^{n} \int_t^T \frac{\partial u}{\partial x_j}(s, N_s) \left( \frac{d}{ds}b^j_s ds + \sigma^j_s \delta X^j_s \right)$$

11
\[-\frac{1}{2} \sum_{j=1}^{n} \int_{t}^{T} \frac{\partial^2 u}{\partial x_j^2}(s, N_s) \frac{d}{ds} \text{Var}(N_s^j) ds. \]  \hspace{1cm} (15)

An application of (8) to the second term on the right hand side of (15) yields

\[ u(t, N_t) = u(T, N_T) - \int_{t}^{T} \left( f(s) + A_1(s)u(s, N_s) + \sum_{j=1}^{n} A_2^j(s) \sigma_j^2 \frac{\partial u}{\partial x_j}(s, N_s) \right) ds \]

\[ - \sum_{j=1}^{n} \int_{t}^{T} \sigma_j^2 \frac{\partial u}{\partial x_j}(s, N_s) \delta X^j_s. \]  \hspace{1cm} (16)

We get (7) by setting \( Y_t := u(t, N_t) \) and \( Z^j_t := -\sigma_j^2 \partial \partial x_j u(t, N_t) \), i.e. \( (Y, (Z^1, \ldots, Z^n)) \) solves (7) and is adapted to \( \mathbb{F} \). As in Section 1.2 we consider this equation for \( t \in [t_0, T] \), for some fixed \( t_0 \geq 0 \).

In order to solve (8) explicitly, we have to assume, in addition to (H1) and (H2) for the kernels \( K^j \), some regularity and integrability conditions. (H5) will be discussed later.

\[ \text{(H3)} \quad \text{There exist constants } c, C > 0 \text{ such that } c < \sigma^j < C, \quad j = 1, \ldots, n, \text{ and } A_1, A, A_2 := (A_1^j, \ldots, A_2^j) \text{ are bounded.} \]

\[ \text{(H4)} \quad g \text{ is continuous, and there exist positive constants } c' \text{ and } \lambda' < \min_{j=1, \ldots, n} \left( 16 \sup_{t \in [0, T]} \text{Var}(N_t^j) \right)^{-1} \text{ such that } |g(x)| \leq c'e^{\lambda'|x|^2} \text{ for all } x \in \mathbb{R}^n. \]

\[ \text{(H5)} \quad \frac{d}{dt} \text{Var}(N_t^j) > 0 \text{ for all } t \in [t_0, T] \text{ and } \int_{t_0}^{T} \left( \text{Var}(N_t^j) - \text{Var}(N_s^j) \right)^{-1/2} dt < \infty, \quad j = 1, \ldots, n. \]

**Theorem 4.1.** Assume that (H1)-(H5) hold, and let \( v(t, z) = (2\pi t)^{-1/2} \exp(-z^2/2t) \). Then \( (Y, (Z^1, \ldots, Z^n)) \) given by (9) solves (7), where the classical solution of (8) is given by

\[ u(t, x) = -\int_{t}^{T} \exp \left( \int_{s}^{t} A_1(r)dr \right) f(s) ds + \exp \left( -\int_{t}^{T} A_1(s) ds \right) \]

\[ \times \int_{\mathbb{R}^n} g(y) \prod_{j=1}^{n} v \left( \text{Var}(N_t^j) - \text{Var}(N_s^j), x_j - \int_{s}^{T} \left( \sigma_j^2 A_2^j(s) - \frac{d}{ds} b_j^2 \right) ds - y_j \right) dy. \]  \hspace{1cm} (17)

An explicit calculation of \( \partial \partial_t u(t, x) \) shows that \( u \) is in fact the (classical) solution of (8). We show now that \( u \) verifies the growth condition (11).

**Lemma 4.2.** Let \( u \) be given by (17). Then there are positive constants \( M \) and \( \lambda < \min_{j=1, \ldots, n} \left( 4 \sup_{t \in [0, T]} \text{Var}(N_t^j) \right)^{-1} \) such that

1) \[ |u(t, x)| \leq Me^{\lambda|x|^2}, \]

2) \[ \left|\frac{\partial u}{\partial x_j^2}(t, x)\right| \leq M \text{Var}(N_T^j) - \text{Var}(N_t^j))^{-1/2}e^{\lambda|x|^2}, \]

3) \[ \left|\frac{\partial^2 u}{\partial x_j^2}(t, x)\right| \leq M \text{Var}(N_T^j) - \text{Var}(N_t^j))^{-1}e^{\lambda|x|^2}. \]
Proof. We give the proof of 1), the proofs of 2) and 3) are similar. We write \( r_j^t \) for \( \sigma^j_s A_j^t(s) - \frac{d}{ds}b_j^t \) and \( D_j^t \) for \( \text{Var}(N_j^t) - \text{Var}(N_j^t) \) in (17). Then, by the change of variables \( z_j = x_j - \int_t^T r_j^s ds - y_j \),

\[
\left| u(t, x) \right| \leq C \int_{\mathbb{R}^n} \exp(\lambda' \left| x - \int_t^T r_j^s ds \right|) \prod_{j=1}^n v(D_j^t, z_j) dy.
\]

Notice that

\[
\int_{\mathbb{R}^n} \exp(\lambda' \left| x - \int_t^T r_j^s ds \right|) \leq \exp(2\lambda' \left| x - \int_t^T r_j^s ds \right|) \exp(2\lambda' |z|^2)
\]

Therefore

\[
\left| u(t, x) \right| \leq C \exp(2\lambda' \left| x - \int_t^T r_j^s ds \right|^2) \int_{\mathbb{R}^n} \prod_{j=1}^n \exp\left(-\frac{1}{2} - 2\lambda' \text{Var}(N_j^t) z_j^2 \right) (2\pi D_j^t)^{-1/2} dz
\]

\[
= C \exp(2\lambda' \left| x - \int_t^T r_j^s ds \right|^2) \prod_{j=1}^n \left(1 - 4\lambda' \text{Var}(N_j^t) \right)^{-1/2}
\]

\[
\leq C \exp(2\lambda' \left| x - \int_t^T r_j^s ds \right|^2) \leq C \exp\left(4\lambda' \left| x \right|^2 \right) \exp\left(4\lambda' \int_t^T r_j^s ds \right)^2,
\]

and 1) follows by choosing \( M = \exp\left(4\lambda' \int_t^T r_j^s ds \right)^2 \) and \( \lambda = 4\lambda' \). ■

Proof of Theorem 4.1 It remains to show that \((Y, Z)\) satisfies the BSDE (7). By the preceding lemma \( u \) satisfies (16) with \( T \) replaced by \( T - \varepsilon \). Since \( \mathbb{E} \exp(2\lambda \left| N_t \right|^2) \) is bounded on \([0, T]\) for \( \lambda < \min_{j=1, \ldots, n} (4 \sup_{t \in [0, T]} \text{Var}(N_j^t))^{-1} \), we obtain

\[
\mathbb{E} \int_t^T |f(s) + A_1(s)u(s, N_s) + \sum_{j=1}^n A_j^2(s) \sigma^j(s) \frac{\partial u}{\partial x_j}(s, N_s)| ds \leq \sum_{j=1}^n \int_t^T (\text{Var}(N_j^t) - \text{Var}(N_j^t))^{-1/2} dt < \infty
\]

for all \( t < T \) by (H5). By continuity of \( u \) and \( N \), the terms in the first line of (16) with \( T \) replaced by \( T - \varepsilon \) converge to the terms in (16) as \( \varepsilon \to 0 \). The divergence integrals converge too in the sense

\[
\mathbb{E} \left[ \int_t^{T-\varepsilon} \sigma_j^t \frac{\partial u}{\partial x_j}(s, N_s) \delta X_j^s F \right] \to \mathbb{E} \left[ \int_t^T \sigma_j^t \frac{\partial u}{\partial x_j}(s, N_s) \delta X_j^s F \right]
\]

for all \( j = 1, \ldots, n \) and \( F \in \mathcal{S} \). ■

Remark. We discuss now the hypothesis (H5). The positivity of \( \frac{d}{dt} \text{Var}(N_j^t) \) means that \( R(t) := \text{Var}(N_j^t) \) is (strictly) increasing on \([t_0, T]\). We note that

\[
\frac{d}{dt} \text{Var}(N_j^t) = \frac{d}{dt} \int_0^t (K^j \cdot \sigma^j)^2 ds = 2 \int_0^t \sigma^j \frac{\partial K_j^j}{\partial t}(t, s) \frac{\partial K_j^j}{\partial u}(u, s) ds du = 2\sigma^j_0 \int_0^t \sigma^j_0 \phi(t, u) du.
\]
Since $\sigma^j > 0$ by (H3), a sufficient condition for $\frac{d}{dt} \text{Var}(N^j_t) > 0$ for all $t \in [t_0, T]$ is $\phi^j > 0$ on $[0, T]^2 \setminus [0, t_0]^2$. This is the case if $\frac{dK^j_t}{dr}(u, s) > 0$ for all $(u, s) \in [0, T]^2, u > s$. For mbm (Example 1) such cases can easily be found for Hurst functions $h$ that are increasing or decreasing on $[0, T]$, but other examples of mbm show that $R$ is increasing on $[t_0, T]$ is possible for suitable values of $t_0$ even if $h$ is only of bounded variation. We note that for fractional brownian motion $B^H$ with Hurst index $H > 1/2$

$$\phi^H(t, u) = \frac{\partial^2}{\partial t \partial u} \mathbb{E}B^H_t B^H_u = C_H \mid t - u \mid^{2H-2} > 0,$$

where $C_H > 0$ is a constant depending on $H$.

Let us comment now on the hypothesis of integrability of $(D^j_t)^{-1/2} := (\text{Var}(N^j_t) - \text{Var}(N^j_{t_0}))^{-1/2}$ near $T$. We have

$$D^j_t = \mathbb{E}\left[\left(\int_0^T \delta W^j_s \int_s^T \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr\right)^2 - \left(\int_0^t \delta W^j_s \int_s^t \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr\right)^2\right]$$

$$= \mathbb{E}\left(\int_0^T \delta W^j_s \int_s^T \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr + \int_0^t \delta W^j_s \int_s^t \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr\right)$$

$$\times \left(\int_0^T \delta W^j_s \int_s^T \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr - \int_0^t \delta W^j_s \int_s^t \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s) dr\right)\right].$$

An explicit calculation shows

$$D^j_t = \int_0^t dr \int_r^T dr' \sigma^j_t \sigma^j_{r'} \phi^j(r, r') + \int_0^t ds \left(\int_t^T dr \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s)\right)^2 + \int_t^T ds \left(\int_s^T dr \sigma^j_t \frac{\partial K^j_t}{\partial r}(r, s)\right)^2$$

$$=: A^1_t + A^2_t + A^3_t.$$

Under the hypothesis (H3) for $\sigma^j$ and if $\phi^j > 0$, a sufficient condition for $\int_0^T (D^j_t)^{-1/2} dt < \infty$ is

$$A^3_t = \int_t^T (K^{*j}_t \sigma^j) \frac{dr}{ds} ds \geq c(T - t)^a$$

for some constant $c > 0$ and $a \in (0, 2)$ as $t \to T$. For fractional brownian motion $B^H$ with $H > 1/2$ this condition is satisfied with $a = H + 1/2$. For the Volterra processes in Examples 1-3 this condition is satisfied with $a = 2h(T)$ if $h$ is such that $\frac{dK^j_t}{dr}(u, s) > 0$, for $(u, s) \in (t_0, T)^2, u > s$.
