## 1 **Introduction**

2 Over the last decade, Human Papillomavirus (HPV) vaccination has been effective in the prevention of  
3 HPV related diseases [1–4].

4 A decrease of HPV 6/11/16/18 infection, genital warts, low-grade cytological cervical abnormalities,  
5 and histologically proven cervical abnormalities has been observed after HPV vaccine introduction.  
6 [4,5] Moreover, results of randomised trials confirmed a high safety profile of HPV vaccines [6].  
7 Maximal benefit is observed among girls vaccinated before HPV exposure in countries that have  
8 achieved high vaccination coverage rates (VCR) [4,7].

9 However, HPV remains a significant source of morbidity and mortality worldwide, emphasizing the  
10 need for vaccination programmes to reach high population coverage [5]. In May 2018, the World  
11 Health Organisation (WHO) called for the elimination of cervical cancer as a public health problem,  
12 and set a target of 90% coverage of HPV vaccination by 2030 in the Global Strategy Towards The  
13 Elimination Of Cervical Cancer As A Public Health Problem drafted in 2019 [8]. In European countries,  
14 HPV vaccination has been gradually introduced in the national immunisation programmes since 2007,  
15 but policies and VCR vary across countries [9,10]. Despite the introduction of free of charge HPV  
16 vaccine in the French immunisation schedule in 2007 [11], HPV VCR has been declining ever since in  
17 France to reach 21% for two doses in 2017 [12]. Other European countries faced suboptimal HPV  
18 VCR, such as Germany [13]. On the other hand, some countries, such as the United Kingdom [14],  
19 have remarkably high HPV VCR. Nevertheless, to the best of our knowledge, no comprehensive  
20 overview of HPV VCR is available for European countries since the VENICE2 report in 2010 [9] and the  
21 review article by Poljak et al. focusing on Central and Eastern European countries in 2013 [10].  
22 Factors linked to such wide variations in VCR between countries in Europe are not well explored in the  
23 literature.

24 Our objectives were therefore to describe HPV VCR in the target population across Europe, as well as  
25 to explore HPV vaccination policies and specific measures taken to facilitate the practical  
26 implementation of the HPV programme in order to reach high uptake in the target population.

## 27 **Methods**

28 A review of national health authorities' websites and published studies was followed by a cross-  
29 sectional survey (prefilled questionnaire) distributed to selected experts from each Member State, in  
30 order to validate publicly available data and explore specific measures taken to facilitate the practical  
31 implementation of the HPV programme in order to reach high uptake in the target population.

### 32 ***Review of national authorities' websites and of the literature***

33 Review of institutional websites and of the literature published on HPV VCR, policies and practical  
34 implementation was conducted for Switzerland and the following 30 European Union/European  
35 Economic Area (EU/EEA) countries: Austria, Belgium, Bulgaria, Croatia, Cyprus, the Czech Republic,  
36 Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia,  
37 Lithuania, Luxembourg, Malta, the Netherlands, Norway, Poland, Portugal, Romania, Slovakia,  
38 Slovenia, Spain, Sweden and the United Kingdom. Belgium was considered as two separate areas in  
39 the results, as Flanders and Walloon-Brussels have different HPV vaccination policies, leading to a  
40 total of 32 geographical areas investigated.

41 Health authorities' websites were reviewed (by NHH, double checked by NA) to identify eligible  
42 reports for each country. 'HPV' and 'human papillomavirus' terms were translated in the corresponding  
43 language and entered in the research tool available on each website. To confirm the target age for  
44 vaccination, the European Centre for Disease Control (ECDC) vaccination schedule tool [15] was used.

45 Peer-reviewed articles published in PubMed from January, 1 2006 to January, 31 2017 and indexed in  
46 Medline were also reviewed to identify studies aiming to describe HPV VCR (for 1-dose and full-course  
47 immunisation), related policies and practical implementation. Languages were restricted to English  
48 and French. Search terms included the following MeSH and usual terms: (((("Papillomavirus  
49 Vaccines"[Mesh] OR "human papillomavirus vaccine, L1 type 16,18"[Supplementary Concept] OR  
50 "human papillomavirus vaccine, TA"[Supplementary Concept] OR "papillomavirus vaccinated"[tw] OR  
51 "papillomavirus vaccination"[tw] OR "papillomavirus vaccinations"[tw] OR "papillomavirus vaccine"[tw]  
52 OR "papillomavirus vaccines"[tw] OR "papilloma virus vaccination"[tw] OR "papilloma virus  
53 vaccinations"[tw] OR "papilloma virus vaccine"[tw] OR "papilloma virus vaccines"[tw] OR "hpv

54 vaccine"[tw] OR "hpv vaccines"[tw] OR "v503"[tw] OR "9v HPV"[tw] OR "9vHPV"[tw] OR "4vHPV"[tw]  
55 OR "qhpv"[tw] OR "2Vhpv"[tw] OR "cervarix"[tw] OR "cervarix"[tw] OR "cervarix's"[tw] OR  
56 "cervarixtm"[tw] OR "cervarixtrade"[tw] OR "Gardasil"[tw] OR "gardasil"[tw] OR "gardasil's"[tw] OR  
57 "gardasil9"[tw] OR "gardasiltrade"[tw] OR "silgard"[tw]) AND "Vaccination/statistics and numerical  
58 data"[Mesh]) OR "Papillomavirus Infections/prevention and control"[Mesh]) AND "<specific name of  
59 country or Europe>").

60 NHHH screened the titles and abstracts of the scientific publications resulting from this search to  
61 assess their eligibility and extracted the data from the selected full-text articles.

62 In November 2017, a standardised form (available upon request to the authors) was used to collect  
63 information about HPV VCR, vaccination policies and practical implementation. Information on the  
64 most recent VCR for 1-dose and full-course immunisation was collected only for females of the target  
65 age in each country. Additionally, the source of the information, i.e. vaccination registries, health care  
66 reimbursement files, reports from national surveys or scientific publications, was collected.  
67 Information about vaccination policies focused on year of introduction of HPV vaccine in the national  
68 immunisation programme, target gender and age (including age for catch-up), type of vaccine used  
69 (bivalent, quadrivalent, or nonavalent), out-of-pocket cost, i.e. cost that are not covered by health  
70 insurance if any, and regulatory aspects, i.e. parental consent required or not, type of consent  
71 (written or oral) if any, and whether provision of information to the recipient is mandatory or not.  
72 Information on vaccination practical implementation focused on mandatory medical prescription prior  
73 to vaccine administration, vaccination settings, dispensing of the vaccine, and measures used to  
74 remind the target population of the vaccination programme. The same information on vaccination  
75 policies and practical implementation specific to males was also collected.

76

### 77 ***Cross-sectional survey***

78 Experts in public health or infection specialists in each country (one per country) were identified by  
79 searching Pubmed using the name of the EU/EEA country and the terms related to HPV used in the  
80 previous review, and contacted by e-mail by CP from November, 20 2017 to January, 22 2018. The

81    aforementioned pre-filled standardized forms were double checked, validated or completed by the  
82    experts from November 2017 to April 2018. In case of data completion, the experts were asked to  
83    provide the scientific publications or reports supporting the additional data. They were also asked to  
84    review the final draft of the manuscript before submission.

85

## 86    ***Statistical analysis***

87    HPV VCR results are reported overall as percentages. Countries were classified into four categories  
88    defined empirically according to their VCR level for at least 1-dose immunisation in females: high  
89    (>70%), moderate (51-70%), low (31-50%) and very low ( $\leq$ 30%). Most recent data on VCR, and  
90    when available, complete schedule VCR rates for the oldest age group was used for classification.

91    To identify vaccination policies and practical implementation steps associated with high HPV VCR in  
92    females, geographical areas' characteristics regarding policies and practical implementation were then  
93    described by their frequency stratified on their VCR category (in females).

94    As no published data on HPV VCR was available in males, vaccination policies and practical  
95    implementation could not be described according to HPV VCR, and were thus described overall in  
96    males.

97

98 **Results**

99 A total of 90 health authorities' websites and related webpages (Supplemental material Tables 1-6)  
100 were browsed for HPV VCR, policies and practical implementation (Figure 1). Similarly, from 217  
101 articles compiled from the PubMed search, a total of 32 (list of references and summary available in  
102 Supplemental material Table 7) were included in the analysis (Figure 2). For the cross-sectional  
103 survey, a total of 71 experts from 31 countries were contacted and 31 experts from 28 countries (all  
104 except Bulgaria, Hungary, and Iceland) agreed to participate.

105

106 ***Description of HPV vaccination coverage rates***

107 HPV VCR estimates, target age and HPV vaccination settings were obtained in 25 (25/32)  
108 geographical areas (Figure 3). HPV VCR was high in ten geographical areas (10/25) : Belgium  
109 Flanders, Finland, Hungary, Iceland, Malta, Norway, Portugal, Spain, Sweden, and the United  
110 Kingdom, moderate in seven areas (7/25): the Czech Republic, Denmark, Ireland, Italy, Luxembourg,  
111 the Netherlands, and Switzerland, low in four areas (4/25): Belgium Walloon Brussels, Germany,  
112 Latvia and Slovenia, and very low in four areas (4/25): Bulgaria, France, Greece, and Poland.

113

114 ***HPV vaccination policies***

115 Vaccination recommendations were usually set at a national level and policies varied widely across  
116 Europe (Table 1). However, implementation was often done at regional level. Accordingly, subnational  
117 differences in vaccination policy were observed in 8/32 areas. For example, subnational differences in  
118 target gender (Saxony region's male vaccination in Germany), age (Belgium, Italy, Spain, the United  
119 Kingdom), and out-of-pocket cost (Poland) were observed.

120

121 ***Year of introduction of HPV vaccination and respective programmes***

122 Of the 32 geographical areas considered, 31 had HPV vaccination recommended in their national  
123 immunisation programme. The first areas which implemented HPV vaccination were France, Germany,  
124 Italy, Spain, and the United Kingdom in 2007. The last one was Estonia, which started HPV  
125 vaccination in 2018.

126 In areas with high VCR, year of introduction of vaccination varied from 2007 for Belgium-Flanders and  
127 Spain to 2014 for Hungary. In areas with very low VCR, year of introduction of vaccination varied from  
128 2007 for France to 2012 for Bulgaria. In Romania, the school vaccination programme implemented in  
129 2008 had been discontinued after three attempts due to low acceptance [16].

130

### 131 *Target age and gender*

132 The target age for vaccination among females ranged from 9 to 15 years old. All areas with high VCR  
133 set the target age between 10 and 13 years old for females, while all areas with very low VCR set it  
134 between 11 and 15 years of age. Seven areas (7/32) recommended gender neutral vaccination, i.e.  
135 vaccination in all males and females: three of these (3/7, i.e. the Czech Republic, Italy, and  
136 Switzerland) in areas with moderate VCR, one (1/4, i.e. Poland) in areas with very-low VCR, and three  
137 in areas with no VCR published, with a target age ranging from 9 to 26 years old.

138

### 139 *Catch-up vaccination programmes*

140 Two main types of catch-up programmes could be distinguished: extended catch-up with a defined  
141 target age or mass catch-up during a limited period of time.

142 Five areas (Finland, Norway Portugal, Spain, and the United Kingdom) with high VCR (5/10) had  
143 offered a mass catch-up during a limited period of time, i.e., at the time of implementation of the HPV  
144 vaccination programme for Finland, Portugal, Spain, and the United Kingdom, and seven to nine years  
145 after implementation in Norway. No such catch-up programme was observed in areas with very low  
146 VCR (0/4).

147 Extended catch-up was less frequent in areas with high VCR (3/10), (i.e. Finland, Sweden, and the  
148 United Kingdom) than in areas with low (4/4) or very low VCR (4/4).

149

### 150 *Type of vaccine authorized and out-of-pocket cost*

151 Three HPV vaccines have been licensed in Europe: bivalent, quadrivalent, and nonavalent marketed as  
152 Cervarix®, Gardasil 4® or Silgard®, and Gardasil 9®, respectively. In most areas, two out of the  
153 three vaccines were marketed (Table 1).

154 HPV vaccine was delivered free of charge for the target population in 28/32 areas. No out-of-pocket  
155 cost was reported for recipients in all areas with high VCR. On the other hand, specific out-of-pocket  
156 costs were observed in three (3/4) very low VCR areas (Greece, Poland, and France). In Greece,  
157 vaccines have been delivered free of charge since 2016 through universal access to healthcare  
158 services [17]. Before 2016, the policy implemented included free access to HPV vaccine only for girls  
159 whose parents were employed, and therefore covered by a health insurance plan. In Poland, HPV  
160 vaccine is at full out-of-pocket cost for individuals, as only mandatory vaccines are free of charge. In  
161 France, the national health insurance reimburses 65% of the cost; a complementary private insurance  
162 (CPI) might refund up to 35% of the total cost, depending on whether people subscribe to a CPI or  
163 not. Approximately 95% of French people subscribe to a CPI and could get a refund, usually after  
164 having paid for the vaccine [18].

165 *Regulatory aspects*

166 Parental consent before vaccination was not reported at the time of investigation for Romania, and  
167 was not required in one (1/10) high VCR area (the United Kingdom) and in three (3/6) moderate VCR  
168 areas (the Czech Republic, Luxembourg, and the Netherlands). In areas requiring parental consent  
169 before vaccination (27/31), this consent was mandatory for girls under 18 years old in 23/27 areas,  
170 and for girls under 16 (alternatively 15 or 14) years old in 4/27 areas, i.e. Portugal and Switzerland  
171 (Slovenia or Latvia, respectively). Parental consent had to be written in 16/26 areas (one area with  
172 missing type of consent).

173 Providing information about HPV vaccine to recipient prior to administration was reported as  
174 mandatory in 26/32 areas.

175 ***Vaccination practical implementation***

176 All geographical areas with high VCR (10/10) have implemented a structured HPV vaccination  
177 programme [19–23]. Six areas with moderate VCR (6/7), i.e. the Czech Republic, Denmark, Ireland,  
178 Italy, Luxembourg, and the Netherlands, had implemented a structured HPV vaccination programme  
179 [9,10,19,20].

180 Among areas with low VCR, three areas (3/4, i.e. Belgium-Walloon-Brussels, Latvia, and Slovenia) had  
181 implemented a structured vaccination programme, while HPV vaccination was opportunistic in  
182 Germany [20]. Finally, among areas with very low VCR, HPV vaccination was mainly opportunistic  
183 (3/4), except for Bulgaria where a structured HPV vaccination programme started in 2012 [10].

184 In areas where HPV vaccination was part of a structured programme, prescription (if any was  
185 required), dispensing, and administration of the vaccine occurred mostly at the same place and at the  
186 same time. In contrast, in all areas where HPV vaccination was opportunistic, except for Germany,  
187 prescription, dispensing, and administration occurred both at different places and at different times.  
188 For example, in France and Greece, parents or girls have to make an appointment with a physician to  
189 get an HPV vaccine prescription; obtain the vaccine from a community pharmacy; and then take  
190 another appointment with their physician for administration of the vaccine.

191 Vaccination practical implementation steps are described in Table 2.

192

193

194 *Medical prescription*

195 Medical prescription was mandatory in 19/32 areas. Mandatory prescription was less frequent in areas  
196 with high VCR (4/10) than in areas with very low VCR (4/4).

197

198 *Vaccination settings*

199 As previously observed for vaccination policies, vaccination practical implementation steps were  
200 usually homogeneous at a national level, but could vary across geographical areas of a country, e.g.  
201 vaccination settings. Subnational differences in vaccination settings were observed in five countries  
202 (Belgium, Italy, Portugal, Spain, and Switzerland).

203 Areas with high VCR have implemented HPV vaccination with both dispensing and administration of  
204 the vaccine in school or in public health centres. Indeed, school immunisation was offered in eight  
205 (8/10) areas with high VCR.

206 By contrast, vaccination was administered in private practices or public community health clinics in  
207 four (4/4) areas with very low VCR.

208

209 *Dispensing of the vaccine*

210 Vaccines were purchased collectively by the country and distributed by local structures in charge of  
211 administering the vaccine, purchased by the physicians in private practices for later administration, or  
212 purchased individually by patients in pharmacies and reimbursed by their health insurance companies.  
213 In areas with high VCR, HPV vaccines were more often systematically dispensed at the place where  
214 they were administered, i.e. in vaccination settings (9/10), than in areas with very low VCR (2/4).

215

216 *Invitations and reminders*

217 Invitations and reminders for HPV vaccine dose were used in 10/10 areas with high VCR, in 5/7 areas  
218 with moderate VCR, and in 2/4 areas with low VCR. No invitations or reminders were used in the four  
219 very low VCR areas.

220 Different types of reminders were used: for example, systematic phone call from public health centres  
221 before the vaccination due date (Italy) or letter to unvaccinated girls (Portugal and the Netherlands).

222

223 ***HPV vaccination in males***

224 HPV VCR data in males was not published for in any area under investigation. HPV vaccination policies  
225 and practical implementation in males are presented in Table 3.

226

227 *HPV vaccination policies*

228 A total of 10/32 areas recommended HPV vaccination in males: 1/10 area (UK) with high VCR in  
229 females, 4/7 (the Czech Republic, Ireland, Italy, and Switzerland) with moderate VCR, 2/4 (France  
230 and Poland) with very low VCR, and 3/7 (Austria, Croatia, and Cyprus) with no VCR. In Germany, only  
231 Saxony had a gender neutral approach.

232 HPV vaccination was either recommended for all males (7/10), in a gender neutral approach, or for  
233 males from specific subgroups (3/10, i.e. the United Kingdom, Ireland, and France). Specific  
234 subgroups consisted of men who have sex with men (MSM), HIV-positive men, and men with other  
235 immunodeficiency disorders.

236 HPV vaccine was free of charge for target groups in six (6/10) areas, i.e. Austria, Croatia, the Czech  
237 Republic, Italy, Switzerland, and the United Kingdom. In France and Ireland, it was free of charge in  
238 specific settings only.

239

240 *HPV vaccination practical implementation*

241 HPV vaccine was administered in schools, public health clinics, or in private practices for males with a  
242 medical prescription in all countries, except for Cyprus and Croatia (8/10). It was dispensed in  
243 vaccination settings in all countries, except for France; indeed, when administered in private practices  
244 in France, the vaccine had first to be dispensed by pharmacies.

245 Reminders were sent to males in Italy only.

246

247 **Discussion**

248 In this comprehensive overview of HPV vaccination coverage, policies and practical implementation in  
249 Europe, HPV VCR was monitored in females but not in males in most of the countries, and showed  
250 wide variations. Variations of respective policies and practical implementation were also observed and  
251 compared across countries to help identify those associated with higher VCR.

252 ***Variation of HPV VCR***

253 One third of included areas had high VCR, and one quarter had low to very low VCR in females, with  
254 no clear North-South or East-West gradient. Due to lack of publicly reported standardised European  
255 surveillance, data on HPV VCR were very difficult to collect, though they might be useful to monitor  
256 the impact of HPV vaccination policies and practical implementation across Europe. Indeed, in their  
257 recent commentary about sustainability of HPV vaccination programmes, Vorters and Van Damme  
258 [24] reported monitoring of HPV VCR as critical to ensure its sustainability. According to the WHO  
259 [25], variation of vaccination coverage rate across EU/EEA countries is not observed for other vaccines  
260 like diphtheria-poliomyelitis-tetanus vaccine (VCR>90%) or measles vaccine (VCR>80%). Although  
261 disease-related factors may partly explain the VCR differences between vaccines, these data suggest  
262 that there may be a substantial room for improvement across Europe for HPV vaccination, especially  
263 considering the objective set by the WHO of 90% HPV VCR by 2030.[8] Seven areas had no VCR data  
264 to report, which was sometimes attributed to a recent implementation in the national immunisation  
265 programme (Estonia, Lithuania), and sometimes to a lack of a monitoring system (Croatia, Slovakia).

266 ***HPV vaccination policies and practical implementation***

267 HPV vaccination policies varied widely across included areas. In areas with high HPV VCR in females,  
268 HPV vaccination was recommended in females at the age of 10-13 years. In areas with very-low HPV  
269 VCR, HPV vaccination was recommended in older girls (age 11-15). Several factors might explain this  
270 finding. Vaccination initiation at an earlier age is known to be associated with higher vaccine  
271 completion rate [26]. Moreover, a French study among 279 general practitioners in 2011 showed that  
272 81% of them were in favour of HPV vaccination although 29% of them felt that the target age (14  
273 years old) was a barrier mainly related to their perceived need to discuss sexual activity with

274 adolescent girls [27]. In this study, half of the general practitioners favourable to HPV vaccination  
275 reported that they would prefer vaccinating girls earlier to avoid such discussion [27]. Discussions  
276 about sexual activity with their daughter have also been reported as a barrier to HPV vaccination in  
277 mother. [28] Accordingly, HPV vaccination at an earlier age might help both general practitioners and  
278 parents disconnect discussion about sexual activity from discussion about HPV vaccine.

279 Implementation of a structured programme was more frequently observed in areas with high or  
280 moderate VCR, and vaccination was mainly opportunistic in areas with very-low VCR. HPV vaccination  
281 practical implementation also varied widely across included areas. In areas with high VCR, vaccination  
282 settings were mainly school-based, HPV vaccine was always dispensed onsite, and reminders were  
283 used. In areas with very-low VCR, HPV vaccine was mainly administered in clinics or in private  
284 practices, but was not always dispensed onsite and reminders were never used. Accordingly, despite  
285 the probable variation across the HPV vaccination programmes implemented in areas with high VCR,  
286 facilitating access to HPV vaccination by increasing onsite vaccine availability, sending reminders, and  
287 relying on schools as the main setting to administer the vaccine might be associated with improved  
288 HPV VCR. Some of these results have already been confirmed by interventional studies. [29–31]

289 A recent literature review of interventions to improve HPV vaccine uptake indeed highlighted three  
290 categories that have proven effective: informational, behavioural, and environmental interventions.  
291 [29] First, informational interventions, delivered individually or collectively, that aim to increase  
292 knowledge on HPV-related diseases are associated with a modest improvement in the vaccination  
293 uptake during implementation of the intervention. However, their effect fades away after they are  
294 discontinued. Our results could not support the effectiveness of information provided to recipients on  
295 HPV vaccine, probably because this information was mandatory in most countries, and was provided  
296 even though it was not mandatory in all countries. [29] Second, behavioural interventions, such as  
297 patient-targeted or provider-targeted reminders, have proven highly effective. [29,30] Interestingly,  
298 provider-targeted interventions are successful in initiating HPV vaccination whereas patient-targeted  
299 interventions are more successful in vaccination completion. [32] Third, environmental interventions  
300 including school-based vaccination are frequently associated with high VCR as they increase access to  
301 vaccination [29,30]. This was noticeable in Switzerland, where vaccination practical implementation

302 and delivery differed by cantons: higher VCR were observed in cantons where the school health  
303 services were involved in the delivery of the vaccine for the target group.[33] Outside of Europe,  
304 school immunisation programmes were also particularly successful in achieving high HPV VCR in  
305 Australia. [34] Availability of the vaccine onsite is also associated with improved HPV vaccine uptake.  
306 [35]

307 In males, HPV vaccination was rarely recommended in included countries, VCR was not available, and  
308 the related policies and practical implementation steps were too heterogeneous to draw any  
309 conclusion about the possible association between HPV vaccination policies or practical  
310 implementation in males and HPV VCR in females. However, the fact that we could not find any data  
311 on HPV VCR in males suggests that HPV VCR was not monitored in males as it was in females, and  
312 might call for better surveillance.

313 As described by Elfström et al. [20], an easily accessible European benchmark on HPV vaccination  
314 policies and their practical implementation combined with a European standardised monitoring of HPV  
315 VCR might help countries struggling with persistent very-low HPV VCR to implement effective HPV  
316 vaccination policies. In this respect, immunisation information systems (or immunisation registries)  
317 might be useful to monitor HPV VCR at a European level [36]. This is of particular importance since  
318 WHO targets a 90% HPV VCR for complete schedule for girls by the age of 15 by 2030, in order to  
319 move towards cervical cancer elimination within a century. [8]

### 320 ***Additional barriers to achieve high HPV VCR***

321 Some of the HPV vaccination policies and practical implementation processes might hinder countries  
322 with very-low VCR from improving their VCR.

323 First, cost of HPV vaccine might be a barrier to achieve high HPV VCR. Indeed, HPV vaccine was free  
324 of charge in countries with high VCR in our overview. On the opposite, individuals were charged out-  
325 of-pockets costs in countries with very-low VCR. For instance, in France, out-of-pocket costs were the  
326 highest in the main vaccination setting, i.e. private practices, though it might not be the main reason  
327 for very-low VCR in France. Indeed, French individuals from higher social class reported more often  
328 than individual from lower social classes a negative opinion about HPV vaccine [37] or hesitancy about

329 vaccines [38]. In Greece, the observed VCR was very low. The financial crisis in 2012 was likely to at  
330 least partly explain the concomitant drop observed in VCR, as the number of uninsured persons  
331 increased at this time. [39] However, universal access to healthcare has been established in 2016,  
332 and might be associated with a future increase of the VCR in the coming years. Similarly, the very-low  
333 VCR observed in Poland might result from the out-of-pocket cost in private practices.

334 Second, mandatory medical prescription might also be a barrier to achieve high HPV VCR. Indeed,  
335 medical prescription was mandatory for the dispensation of HPV vaccine in all countries with very-low  
336 VCR, which can complicate the process by adding additional steps to obtain the vaccine. In countries  
337 with high VCR, mandatory medical prescription was less frequently observed in our overview.

338 Last but not least, some countries were faced with HPV vaccine controversies leading to VCR drop.  
339 From 2013, Denmark experienced growing media attention on HPV vaccine safety and an increase of  
340 reported alleged adverse events following immunisation. Furthermore, a television programme  
341 broadcasted in 2015 featuring girls with disabling symptoms allegedly linked to HPV-vaccination  
342 caused a marked decline in vaccine uptake to under 50%. Denmark had successfully addressed these  
343 issues by running an informational campaign, mostly online, featuring a website and a Facebook page  
344 [40]. Similarly, in Ireland, misinformation was spread by some lobby groups on social media in 2015,  
345 and a documentary on national television has raised parental concerns resulting in VCR decline. [41]  
346 Ireland rapidly organised an informational campaign targeting parents and health professionals, which  
347 led to an increase in HPV vaccine uptake in the school year 2017/2018.[42]

## 348 **Limitations**

349 Causality to link HPV policies and practical implementation steps to VCR is difficult to establish due to  
350 the cross-sectional, descriptive, and ecological design of this overview. In addition, the wide range of  
351 political and legislative settings observed in Europe might have led to various interpretations of the  
352 variables we aimed to collect, leading to information bias. However, the use of a standardised form  
353 with a clear definition of each one of the collected variables probably limited this bias. In addition, to  
354 overcome this potential limitation, the form, once prefilled with the literature and websites' review  
355 results, was sent to the experts; tailored additional information was provided to the experts if needed.

356 Another information bias might have occurred when assessing HPV VCR in some countries, because of  
357 the variety of methods used to estimate VCR across countries [20]. However, validation of the results  
358 by native experts increased the probability that the data adequately reflected the vaccine uptake in  
359 the target country.

360 Finally, we focused only on HPV vaccination policies and practical implementation. However, HPV VCR  
361 is also influenced by sociocultural factors and individual characteristics, as reported in Switzerland  
362 [33], that might explain part of the observed VCR variation.

### 363 **Conclusion**

364 This study explored health policies and practical implementation processes that might explain variation  
365 in HPV vaccination uptake across 31 European countries. We observed that structured vaccination  
366 programmes targeting females early in adolescence and free of charge vaccine administration were  
367 more frequently observed in high VCR countries than in very-low VCR countries, which therefore may  
368 be important factors for achieving high vaccine uptake. Facilitating access to HPV vaccination by  
369 increasing onsite vaccine availability, sending invitation and reminders to attend for vaccination, and  
370 relying on schools as the main setting to administer the vaccine might also be associated with  
371 improved HPV VCR. Monitoring of both HPV vaccination policies and practical implementation and HPV  
372 VCR at a European level, as well as sharing experiences between countries might be of major public  
373 health relevance to achieve consistently high HPV VCR across Europe.

374

375 **Authors' contribution**

376 NT, CP and NA initiated the study. NHNG and NA drafted the protocol, that was reviewed by  
377 all authors. NHNG collected the data, which were double checked when needed by NA. CP  
378 contacted all national representatives. NHNG interviewed the national representatives. NHNG  
379 analysed the data, under the supervision of NA. All authors helped interpret the data. NHNG  
380 and NA drafted the manuscript, which was reviewed by all authors.

381 **Conflict of interest:** No conflict of interest to declare for all authors.

382 **Funding statement:** None, this study was conducted as part of our routine work.

383 **Disclaimer**

384 The views and opinions expressed herein are the authors' own and do not necessarily  
385 state or reflect those of ECDC. ECDC is not responsible for the data and information  
386 collation and analysis and cannot be held liable for conclusions or opinions drawn.

i Except in schools

ii The invitation letter came with an appointment scheduled during off-school hours in the health centre.

iii Available in private practices if there is a convention with Ministry of Health

iv Reminders were emailed to unvaccinated patients with delays in vaccination schedule

v Except in schools

vi In 2014, there was a National intervention of written reminders using the Danish Vaccination Register that were sent out at age 14 if doses of vaccines were missed by that age

vii Except in schools

---

viii Vaccine delivery depends on cantons

ix Variation by regions

<sup>x</sup> Free choice for the schools to offer HPV vaccination, and approximately 30% schools in Wallon Brussels didn't offer HPV vaccination.

xi If the recipient is statutory insured, the vaccine is available at the GP. If the recipient is privately insured, the vaccine has to be collected at the pharmacy.

xii In case of regional programme, vaccination can be administered in schools.

**Table 3: HPV vaccination policies and practical implementation for males and other specific at-risks groups in European countries in 2017**

Countries	HPV vaccination policies					
	Target groups	Specific groups	Target age	Type of vaccine used	Out-of-pocket cost	Mandatory medical prescription
Austria	All	NA	9-12	4v, 9v	Free of charge for 9-12, Reduced cost for 13-15, Full price >15	Y
