HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Analysis of systematic errors in Mueller matrix ellipsometry as a function of the retardance of the dual rotating compensators

What is the best configuration for the compensators ?

A dual rotating compensators ellipsometer has been developed. It is based on the optical PC₁SC₂A configuration, where C₁ and C₂ are the synchronized continuously rotating compensators [1]. The systematic errors if the compensators are quarter-wave plates have been already studied [2]. Smith [3] has demonstrated that the optimum retardance of a dual-rotating-retarder (DRR) instrument must be equal to 127° compared to the quarter-wave (90°) retarders generally used.

In these conditions random errors are optimized. $\longleftrightarrow$ What about systematic errors ?

The PC₁SC₂A ellipsometer

The detected light has the following form :

$$I = I_0 \left[a_0 + \sum_n (a_{2n} \cos 2nC + b_{2n} \sin 2nC) \right]$$

- $C = \omega t$ is related to C₁ and C₂ by the relations: $C_1 = m_1(C - C_{S1})\omega t$ and $C_2 = m_2(C - C_{S2})\omega t$ respectively.
- C₁ and C₂ are the angles of the fast axes of the first and second compensators at time t.
- C_{S1} and C_{S2} are imposed by the mechanical assembly and correspond to the azimuth of the fast axis of the compensators with respect to the plane of incidence at the beginning of the acquisition.
- The frequency of the two compensators are synchronized and related to the base mechanical frequency ω by the two integers m₁ and m₂. In our configuration, m₁=3 and m₂=5.
- 24 non-zero Fourier coefficients allow to deduce all normalized coefficients of the matrix.

Conclusions

Single zone measurement (Table 1)

- $\delta_1 = \delta_2 = 127^\circ$ are well suited for errors due to δA , δP , δC_{S1} , δC_{S2} (first and second order).
- For $\delta\delta_1$ and $\delta\delta_2$ (first order), 11 coefficients are in the best condition with $\delta_1 = \delta_2 = 127^\circ$ and 4 coefficients are in the best condition with $\delta_1 = \delta_2 = 90^\circ$.
- $\delta_1 = \delta_2 = 90^\circ$ are well suited for $\delta\delta_1^2$ and $\delta\delta_2^2$ (second order).

4-zone measurement (Table 2)

- There is **no difference** between $\delta_1 = \delta_2 = 127^\circ$ or 90° for errors due to δA , δP , δC_{S1} and δC_{S2} (the first and the second order).
- For $\delta\delta_1$ and $\delta\delta_2$ (first order), 8 coefficients are in the best condition with $\delta_1 = \delta_2 = 127^\circ$ and 4 coefficients are in the best condition with $\delta_1 = \delta_2 = 90^\circ$.
- $\delta_1 = \delta_2 = 90^\circ$ are well suited for $\delta\delta_1^2$ and $\delta\delta_2^2$ (second order).

The systematic errors

The measured Mueller matrix, $M_{measured}$, is related to the Mueller matrix of the sample, M_{sample} , by :

$$M_{measured} = M_{sample} + \delta M = M_{sample} + \frac{\partial M}{\partial x} \delta x + \frac{1}{2} \frac{\partial^2 M}{\partial x^2} \delta x^2 + \dots$$

where x is the perturbation and δM is the systematic error matrix due to the perturbation. For this study, the effect of each error are studied individually and the remaining optical elements of the ellipsometer are assumed to be ideal.

2nd order
1st order

The azimuthal errors are :

- the analyzer, δA
- the polarizer, δP
- the compensators, δC_{S1} and δC_{S2}

The birefringence errors are :

- the (optional) windows, δW_1 and δW_2
- the compensators, $\delta\delta_1$ and $\delta\delta_2$

Some errors can be removed if a 4-zone averaging measurement method is performed. It is defined as:

$$(M_{ij})_{sample} = \frac{1}{4} \sum_{A; A+\pi/2} \sum_{P; P+\pi/2} (M_{ij})_{measured}$$

Systematic errors (1st and 2nd order) obtained with $\delta_1 = \delta_2 = 90^\circ$ and $\delta_1 = \delta_2 = 127^\circ$ for single measurement (Table 1) and 4-zone averaging measurement (Table 2).

For δC_{S1} , δC_{S2} , δC_{S1}^2 and δC_{S2}^2 , the errors are defined in the simple case, $C_{S1} = C_{S2} = 0^\circ$.

errors are smaller if $\delta_1 = \delta_2 = 127^\circ$

errors are smaller if $\delta_1 = \delta_2 = 90^\circ$

= : errors are identical ($\delta_1 = \delta_2 = 127^\circ$ or 90°)

0 : errors are null ($\delta_1 = \delta_2 = 127^\circ$ or 90°)
