To investigate traces of ancient anthropic activities in soils and landscapes, on areas where archaeological structures have not yet been detected.

Context of the study

The Saint-Mont site

A relatively inhospitable mountain:
- hard climate, steep slopes,
- on acid soils developed from a granitic rock,
- nowadays covered by forests.

Remains suggest human presence for at least 1400 years:
- At the top, the monastery Haberland (from the 7th century to the French Revolution) and a late antique occupation (Chenal 2016).
- Monumental enclosure dry-stones walls of unknown age (Grzeszniak, 2019).
- The « Point des Fées »: An enigmatic structure.

Objectives

Joint work involving soil scientists, archaeologists, geographers, geologists and computer scientists

Approaches from the landscape to the microscopic scales.

Software tools to extract and analyse geometric structures in LiDAR data.

Field prospections / rocks and soils descriptions and sampling, floristic surveys.

Studies along gradients from highly to poorly human impacted areas.

Material and methods

Archaeological data

LiDAR image to locate platforms connected to archaeological structures and all our sampling stations: subsoils, pits and rock outcrops.

Results

Interactive extraction of linear structures from LiDAR raw data

Development of new algorithms based on digital geometry tools to directly process 3D ground points and get rid of digital terrain model approximations in forested areas (Even and Ngo, 2020).

Immediate visualization of extracted structure, cross and longitudinal profiles and of geometric estimations (height or depth, width, volume,...).

Time and precision performance evaluated on well controlled structures: forest roads (Even and Ngo, 2021).

Usability assessed on archaeomorphological enclosure walls and old hollies (Even et al., 2021).

Landscape and geological materials

A tectonic and glacial heritage

- 3 axes of fracturing highlighted from rock outcrops and preferential feldspar orientations in thin-sections measurements.

- Tectonic fracturing guided the action of the Quaternary. Both factors structure the massif and control its triangular shape.

Geological heritage

The rock descriptions (macroscopically and in thin sections) confirm that most of the Saint-Mont is composed of Remiremont granite (Vincent, 1970).

- New informations, not noted on the geological map:
  * At the bottom of the granitic massif.
  * A large vein of aplite (supposed by the presence of aplite fragments in our studied profiles).

Soil covers

1. Soils not clearly disturbed

- Far from any known archaeological remains, two main types of soils develop on granite:
  * Humic alinols (BRH) → Coastal-humic Natrustoll
  * Rankosols (RP) → Acidic (pHunkor 4 in the orgo-mineral horizon) and desaturated soils (5/15/15%)

- Strict acidiphil vegetation

- Reference soils not affected by ancient activities

2. Highly anthropised soils on platform P

- Anthroposol (RP) « Transformed on a man made terrace » → Anthrosol with a pristic horizon (H8R)

- Almost全社会 dipartite structure

- Phytoliths: classic - open woodland, landscape composition

- Anthropogenous artifacts

- No organic, nor anthropogenic → natural soil mineral horizon?

- Weathered materials compounds.

- Black unit (0.1m thick) very rich in organic matter. Almost neutral pH (pH 8.016 in the orgo-mineral horizon) and saturated soils (5/10/5%)

- Acidline to neuroline vegetation

- Cues of long term tillage and regular manure inputs

3. Other evidence of ancient human influence on soils?

- Soil water values measured on the orgo-mineral horizons of the different stations (shallow pits (1) and pits if 34). All stations are anisotropic, except F9 on bussanght stations 29, 31 and 32 on aplite.

- pH water values measured on the orgo-mineral horizons of the different stations (shallow pits (1) and pits if 34). All stations are anisotropic, except F9 on bussanght stations 29, 31 and 32 on aplite.

- To detect some anomalies:
  * Light when pH is between 4 and 5
  * More significant when pH is > 5

- Easily related to the long-lasting human occupation on the summit.

- More surprising on some western or southern platforms:
  * Leads for future archaeological studies.

Conclusion and perspectives

Our results confirm:
- A very strong imprint of historical human activities on soils close to the summit part of the massif.
- An heritage on the western slope mainly from natural glacial and pedogenetic processes.
- Possible other human activities on some western or southern platforms.

We hypothesize that the weak anomalies are due to older and/or different human activities than those that took place at the top of Saint-Mont (like breeding).

Other analyses are being acquired and interpreted on soils, rocks and LiDAR images.
