# A New PWM Strategy Based on a 24-Sector Vector Space Decomposition for a Six-Phase VSI-Fed Dual Stator Induction Motor

Khoudir Marouani, Lotfi Baghli, Djafar Hadiouche, Abdelaziz Kheloui, and Abderrezak Rezzoug

Abstract—This paper presents a new space vector pulsewidth 6 modulation (SVPWM) technique for the control of six-phase 7 voltage source inverter (VSI)-fed dual stator induction machines 8 (DSIM). A DSIM is an induction machine which has two sets 9 of three-phase stator windings spatially shifted by 30 electrical 10 degrees and fed by two three-phase VSIs. Despite their advantage 11 of power segmentation, these machines are characterized by large 12 zero sequence harmonic currents, and in particular those of order 13  $6k \pm 1$ , which are due to the mutual cancellation between the 14 two stator windings. The proposed SVPWM scheme, while easy 15 to implement digitally, reduces significantly these extra stator 16 harmonic currents. Experimental results, collected from a 15 kW 17 prototype machine controlled by a digital signal processor are 18 presented and discussed.

19 Index Terms—Dual stator induction machines (DSIM), 20 six-phase voltage source inverter (VSI), space vector pulsewidth 21 modulation (SVPWM).

### I. INTRODUCTION

22

TOWADAYS, electrical machine drives are widely used in industrial applications and transportation systems such 25 as electric/hybrid vehicles, traction locomotives and electric 26 propulsion ships, where high-power levels in conjunction with 27 high-performance requirements are more and more demanded. To achieve these high ratings, there are two possible ap-29 proaches; one focuses on the converter side by increasing 30 the number of output voltage levels and the other one on 31 the machine side by increasing the number of phases. In the 32 first approach, the idea is to divide the high dc bus voltage 33 into multiple low levels and therefore to distribute the high 34 power required among cells of reduced-voltage power switches 35 without the problem of dynamic voltage sharing encountered 36 in the series connection of active devices. However, increasing 37 the number of inverter levels adds to the control complexity and 38 may introduce some voltage imbalance problems [1]–[3]. It is a 39 solution well suited for high-power and high-voltage utility ap-

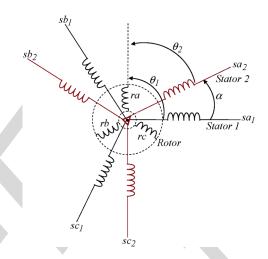

Fig. 1. DSIM windings.

plications. For adjustable speed drives, however, an alternative 40 approach is to use a multiphase machine, i.e., a machine with 41 more than three phases in the stator, since the number of phases 42 is not imposed anyway, given that the machine is connected 43 to the electric supply through a dc/ac converter. The number of 44 phases could be used instead as an additional degree of freedom 45 in the overall system design [4].

Although the answer to the question whether it is better to use 47 a multilevel inverter-fed three-phase machine or a multiphase 48 machine depends on the application, it is undeniable that the 49 latter option offers several advantages which may make it 50 appear very attractive. In fact, the most significant features are 51 a low torque ripple, a reduction in the power per phase and 52 fault-tolerance capability. Other interesting advantages can be 53 pointed out, such as a better torque production per ampere 54 for the same machine volume, higher efficiency and improved 55 reliability [5], [6].

A common type of multiphase machine is the dual stator 57 induction machine (DSIM), where two sets of three-phase 58 windings, spatially phase shifted by 30 electrical degrees, share 59 a common stator magnetic core as shown in Fig. 1.

Due to the development of fast switching power semicon- 61 ductor devices, voltage source inverters (VSIs) are preferred 62 in variable speed machine drives. As VSI-fed multiphase ma- 63 chines are gaining increasing interest for high-power applica- 64 tions, various pulsewidth modulation (PWM) techniques have 65 been developed accordingly, as they strongly affect the overall 66 inverter efficiency and output voltage waveform quality.

In a VSI-fed DSIM, the two stator windings are mutually 69 coupled and small unbalances in the two supply voltages may 70 generate high currents [7]. Furthermore, because of the low 71 impedance seen by the voltage harmonic components generated 72 by the switched voltage waveforms, harmonic currents of high 73 level are circulating uselessly in the two stator windings, adding 74 to the overall losses and therefore to the semiconductor devices 75 ratings [8], [9].

To minimize these extra harmonic currents in a six-phase VSI-fed DSIM, a new 24-sector PWM technique is proposed 8 in this paper and tested on a 15 kW laboratory machine. The 9 digital implementation is carried out on a DS1104 dSPACE 80 controller board. A comparative study between the proposed 81 technique and similar space vector PWM (SVPWM) techniques 82 [5], [10], based on analytical harmonic current analysis, is also 83 developed and discussed.

### II. MACHINE MODEL

The machine model is based on the assumption that space 86 harmonics and magnetic saturation are negligible, and that the 87 two stator three-phase windings are identical and symmetrical 88 with the two neutrals being isolated. In order to derive a practical model suitable for control, a decoupling transformation 90 matrix is used, as proposed in [5]–[7]. The matrix has the 91 following form:

$$[Ts]^{-1} = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} & 0\\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} & \frac{1}{2} & \frac{1}{2} & -1\\ 1 & -\frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & 0\\ 0 & -\frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & \frac{1}{2} & \frac{1}{2} & -1\\ 1 & 1 & 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 1 & 1 \end{bmatrix}.$$

$$(1)$$

By applying (1) to the voltage vector equations, the overall machine model is transformed into three decoupled submodels, written in three independent space coordinates, identified as 95  $(\alpha-\beta)$ , (x-y), and  $(o_1-o_2)$ , respectively.

96 The machine voltage submodel in  $(\alpha - \beta)$  coordinates can be 97 written as:

$$\begin{bmatrix} v_{s\alpha} \\ v_{s\beta} \\ v_{r\alpha} \\ v_{r\beta} \end{bmatrix} = \begin{bmatrix} R_{s} & 0 & 0 & 0 \\ 0 & R_{s} & 0 & 0 \\ 0 & M \dot{\theta} & R_{r} & L_{r} \dot{\theta} \\ -M \dot{\theta} & 0 & -L_{r} \dot{\theta} & R_{r} \end{bmatrix} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ i_{r\alpha} \\ i_{r\beta} \end{bmatrix} + \begin{bmatrix} L_{s} & 0 & M & 0 \\ 0 & L_{s} & 0 & M \\ M & 0 & L_{r} & 0 \\ 0 & M & 0 & L_{r} \end{bmatrix} \frac{d}{dt} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ i_{r\alpha} \\ i_{r\beta} \end{bmatrix}$$
(2)

98 where  $\stackrel{\bullet}{\theta}=\Omega_{\rm m}$  is the rotor mechanical speed, and  $L_{\rm s}=L_{\rm ls}+$  99  $3L_{\rm ms},~L_{\rm r}=L_{\rm lr}+(3/2)L_{\rm mr},~M=(3/\sqrt{2})M_{\rm sr}.~L_{\rm ls}$  and  $L_{\rm lr}$  100 are the stator and rotor leakage inductances in  $(\alpha-\beta)$  coordinates, respectively.

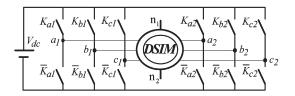

Fig. 2. Six-phase VSI fed DSIM.

The DSIM  $(\alpha - \beta)$  submodel expressed in the stationary 102 reference frame is similar to the three-phase induction machine 103 model [11].

The machine voltage submodel in (x-y) coordinates is 105 given by:

$$\begin{bmatrix} v_{sx} \\ v_{sy} \end{bmatrix} = \begin{bmatrix} R_{s} & 0 \\ 0 & R_{s} \end{bmatrix} \begin{bmatrix} i_{sx} \\ i_{sy} \end{bmatrix} + \begin{bmatrix} L_{lsxy} & 0 \\ 0 & L_{lsxy} \end{bmatrix} \frac{d}{dt} \begin{bmatrix} i_{sx} \\ i_{sy} \end{bmatrix}$$
(3)

where  $L_{{\rm ls}xy}$  is the transformed stator leakage inductance in 107 (x-y) coordinates.

The machine voltage submodel in  $(o_1-o_2)$  coordinates is 109 expressed as follows:

$$\begin{bmatrix} v_{\rm so1} \\ v_{\rm so2} \\ v_{\rm ro} \end{bmatrix} = \begin{bmatrix} R_{\rm s} & 0 & 0 \\ 0 & R_{\rm s} & 0 \\ 0 & 0 & R_{\rm r} \end{bmatrix} \begin{bmatrix} i_{\rm so1} \\ i_{\rm so2} \\ i_{\rm ro} \end{bmatrix} + \begin{bmatrix} L_{\rm lso} & 0 & 0 \\ 0 & L_{\rm lso} & 0 \\ 0 & 0 & L_{\rm lr} \end{bmatrix} \frac{\mathrm{d}}{\mathrm{d}t} \begin{bmatrix} i_{\rm so1} \\ i_{\rm so2} \\ i_{\rm ro} \end{bmatrix}$$

$$(4)$$

where  $L_{\rm lso}$  is the transformed stator leakage inductance in 111  $(o_1-o_2)$  coordinates.

The electromagnetic torque of the DSIM is expressed only 113 in terms of stator and rotor  $(\alpha-\beta)$  current components, since 114 the (x-y) and  $(o_1-o_2)$  counterparts do not contribute to the 115 electromechanical energy conversion, as shown by (3) and (4). 116 The expression of the electromagnetic torque is then as follows: 117

$$T_{\rm e} = pM(i_{\rm s\beta}i_{\rm r\alpha} - i_{\rm s\alpha}i_{\rm r\beta}) \tag{5}$$

118

where p is the number of pole pairs.

The (x-y) and  $(o_1-o_2)$  current components do not con- 120 tribute to the air-gap flux linkages. Hence, they are limited only 121 by the stator resistance and leakage inductance [12], [13]. They 122 produce only losses and therefore must be kept equal to zero or 123 as small as possible.

The transformed voltage equations in the three subframes 125 are well decoupled and, as a result, both machine analysis and 126 control are greatly simplified.

The drive system is a six-phase VSI fed DSIM, as shown 130 in Fig. 2. A combinatorial analysis of the inverter switch 131 states shows 64 switching modes. Thus, 64 different voltage 132 vectors can be applied to the machine. Each voltage vector is 133 represented by a decimal number corresponding to the binary 134 number  $(K_{c2}K_{b2}K_{a2}K_{c1}K_{b1}K_{a1})$ , which gives the state of 135

136 the upper switches. By using the  $(6\times 6)$  transformation matrix 137  $[Ts]^{-1}$ , each voltage vector can be decomposed into  $(\alpha-\beta)$ , 138 (x-y), and  $(o_1-o_2)$  voltages. The  $(o_1-o_2)$  ones are all equal 139 to zero because the neutrals  $(n_1,n_2)$  of the two winding sets 140 are isolated. So the SVPWM strategy operates in two complex 141 planes  $(\alpha-\beta)$  and (x-y). Four variables need to be controlled 142 simultaneously during each sampling period, by generating 143 maximum  $(\alpha-\beta)$  and minimum (x-y) voltage amplitudes. 144 Therefore, during each sampling period, a set of four active 145 voltage vectors must be chosen to fulfil these two conditions, 146 according to the reference voltage vector location. There are 147 numerous ways for choosing such a set.

### 148 A. Six-Phase SVPWM Techniques

The principle of the PWM control techniques proposed in 150 [5] and [10] is to choose switching sequences in such a way 151 that two consecutive nonzero voltage vectors are practically 152 opposite in phase in the (x-y) plane. In this way, each change 153 in the applied vectors leads to a sequence of increases and 154 decreases in (x-y) currents around zero. Moreover, in order 155 to minimize (x-y) harmonic currents and maintain the lowest 156 switching frequency, there are different choices to allocate 157 zero voltage vectors (0, 7, 56 or 63) within the switching 158 sequences. Thus, the switching sequences presented in [10] lead 159 to continuous and discontinuous modulation techniques and, 160 consequently, to different harmonic distortion characteristics. 161 A modulation technique is continuous when on/off switching 162 occurs within every sampling period, for all inverter legs and 163 all sectors. A modulation technique is discontinuous when one 164 (or more) inverter leg stops switching, i.e., the corresponding 165 phase voltage is clamped to the positive or negative dc bus for 166 at least one sector [14].

### 167 B. 12-Sector SVPWM Technique

In the SVPWM technique addressed in [5], only the  $(\alpha-\beta)$  169 voltage vectors having maximum magnitude (45, 41, 9, 11, 170 27, 26, 18, 22, 54, 52, 36, 37) are employed to synthesize 171 the reference voltage vector  $v_{s\alpha\beta}^*$ . These voltage vectors divide 172 the  $(\alpha-\beta)$  plane into 12 sectors and each sector is  $\pi/6$  rad, 173 as shown in Fig. 3. For example, voltage vectors 45, 41, 9, 174 and 11 are selected when the reference voltage vector is located 175 in sector 1. As shown in Fig. 4, continuous and discontinuous 176 modulation techniques can be obtained according to the switch-177 ing sequences given below.

178 1) Continuous Modulation C6  $\phi$  SVPWM12: For example, 179 when the reference voltage vector is located in sector 1, a con-180 tinuous modulation technique (C6  $\phi$  SVPWM12) is obtained 181 with the following sequence:

$$|7-45-41-56-9-11-7|7-11-9-56-41-45-7|$$
.

182 2) Discontinuous Modulation D6  $\phi$  SVPWM12-A: For the 183 same sector 1, a discontinuous modulation technique (D6  $\phi$  184 SVPWM12-A) can be obtained with the following sequence:

$$|7-45-41-9-11-7|7-11-9-41-45-7|$$
.

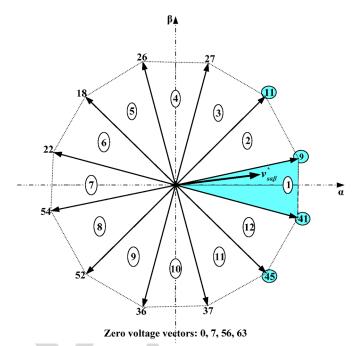

Fig. 3. Presentation of the inverter voltage vectors having maximum magnitude in  $(\alpha - \beta)$  plane.

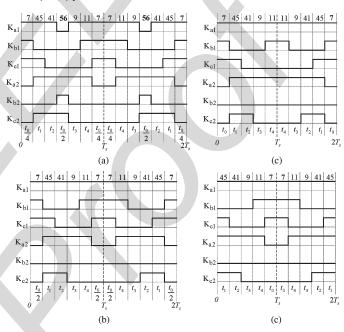

Fig. 4. Twelve-sector SVPWM switching sequences when the reference voltage vector is located in sector 1. (a) C6  $\phi$  SVPWM12. (b) D6  $\phi$  SVPWM12-A. (c) D6  $\phi$  SVPWM12-B1. (d) D6  $\phi$  SVPWM12-B2.

3) Discontinuous Modulation D6  $\phi$  SVPWM12-B1: In the 185 D6  $\phi$  SVPWM12-B1, the zero-voltage vectors are applied at the 186 beginning and at the end of the switching sequence as follows: 187

$$|7-45-41-9-11|11-9-41-45-7|$$
.

4) Discontinuous Modulation D6  $\phi$  SVPWM12-B2: In the 188 D6  $\phi$  SVPWM12-B2, the zero-voltage vectors are applied in 189 the middle of the switching sequence as follows:

$$|45-41-9-11-7|7-11-9-41-45|$$
.

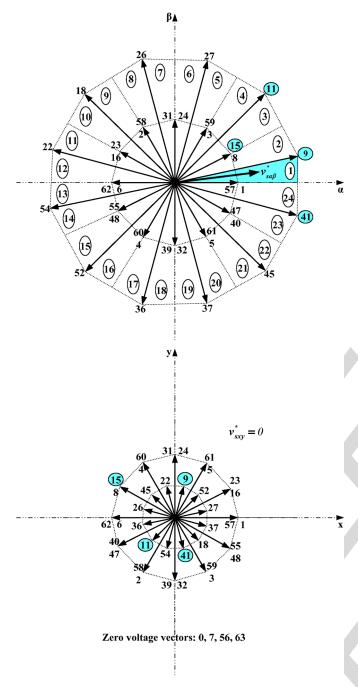

Fig. 5. Presentation of the inverter voltage vectors having maximum and half magnitude in  $(\alpha - \beta)$ , and (x - y) planes.

### 191 C. Proposed 24-Sector SVPWM Technique

As shown in Fig. 4, the switching pattern corresponding 193 to the switching sequences of the 12-sector PWM techniques 194 presents asymmetrical waveforms and usually more than two 195 transitions (from low to high or from high to low) occur on 196 the corresponding PWM outputs within a sampling period, 197 which increases the switching frequency of the inverter legs 198 and causes difficulties for digital signal processor (DSP) im-199 plementation of these strategies. Accordingly, some additional 200 adaptations in DSP programs are necessary to ensure successful 201 experiments [15], [16].

To overcome these drawbacks, the new 24-sector SVPWM 203 technique proposed in this paper combines the maximum

magnitude  $(\alpha - \beta)$  voltage vectors and the ones with half 204 magnitude (1, 57, 8, 15, 3, 59, 24, 31, 2, 58, 16, 23, 6, 205 62, 48, 55, 4, 60, 32, 39, 5, 61, 40, 47) generated by one 206 inverter. These voltage vectors divide the  $(\alpha - \beta)$  plane into 207 twenty four  $\pi/12$ -rad sectors, as shown in Fig. 5. In each 208 sampling period, the reference voltage vector is achieved by 209 selecting a set of three voltage vectors among those having 210 maximum magnitude and a fourth vector among the ones with 211 half magnitude. For example, voltage vectors 41, 9, 11 and 15 212 are selected when the reference voltage vector is located in 213 sector 1. Then, the voltage vectors applying times:  $t_1$ ,  $t_2$ ,  $t_3$  and 214  $t_4$  are obtained as explained in Appendix A. For the remaining 215 time  $t_0 = T_s - (t_1 + t_2 + t_3 + t_4)$ , zero state vectors (0, 7, 56 216 or 63) are applied. Consequently, simple PWM outputs with 217 symmetrical waveforms are obtained. As shown in Fig. 6, 218 only two transitions or less (from low to high or from high 219 to low) occur on the corresponding PWM outputs within a 220 sampling period. This fact decreases the switching frequency 221 of the inverter legs and allows easy DSP implementation. The 222 switching sequences and the corresponding applying times for 223 all sectors are presented in Table I. It should also be noticed 224 that both continuous and discontinuous modulation techniques 225 can be obtained with this new 24-sector SVPWM scheme. This 226 is achieved by selecting the appropriate zero voltage vector 227 locations within the switching sequence.

1) Continuous Modulation C6  $\phi$  SVPWM24: Continuous 229 PWM technique (C6  $\phi$  SVPWM24) can be obtained for all sec-230 tors by selecting the switching sequences presented in Table I. 231 As an example, when the reference voltage vector is located 232 in sector 1, a C6  $\phi$  SVPWM24 is obtained by selecting the 233 following sequence:

$$|56-41-9-11-15-7|7-15-11-9-41-56|$$
.

- 2) Discontinuous Modulation D6  $\phi$  SVPWM24-B1 and B2: 235 Two discontinuous PWM schemes can be obtained through the 236 appropriate positioning of the zero voltage vectors. In sector 1, 237 the examples are as follows.
  - 1) D6  $\phi$  SVPWM24-B1: The first discontinuous modulation 239 technique can be obtained by placing the zero voltage 240 vector both at the beginning and at the end of the switch-241 ing sequence, as follows:

$$|\mathbf{56}-41-9-11-15|15-11-9-41-\mathbf{56}|.$$

2) D6  $\phi$  SVPWM24-B2: The second discontinuous mod- 243 ulation technique is obtained by placing the zero volt- 244 age vector in the middle of the switching sequence, as 245 follows:

$$|41-9-11-15-7|7-15-11-9-41|$$
.

3) Switching Sequences and Applying Time Selection: For 247 optimal DSP implementation and low algorithm execution time, 248 the applying times  $(t_1, t_2, t_3, \text{ and } t_4)$  computation can be 249 simplified by an offline calculation for all sectors in the same 250 manner as for sector 1. As a result, within each sampling period, 251 there is a total of only 12 coefficients  $T_i$  to be calculated in (6). 252

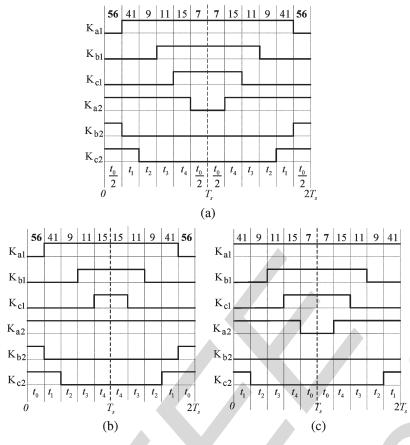

Fig. 6. Twenty-four-sector SVPWM switching sequences when the reference voltage vector is located in sector 1. (a) C6  $\phi$  SVPWM24. (b) D6  $\phi$  SVPWM24-B1. (c) D6  $\phi$  SVPWM24-B2.

253 Table I describes the C6  $\phi$  SVPWM24 switching sequences and 254 applying time selection according to the sector number in the 255  $(\alpha-\beta)$  plane.

$$\begin{bmatrix} T_1 \\ T_2 \\ T_3 \\ T_4 \\ T_5 \\ T_6 \\ T_7 \\ T_8 \\ T_9 \\ T_{10} \\ T_{11} \\ T_{12} \end{bmatrix} = \frac{T_s}{2V_{dc}} \begin{bmatrix} \sqrt{3} - 2 & 1 \\ 1 & -\sqrt{3} \\ 1 & \sqrt{3} - 2 \\ 0 & 2 \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ -(\sqrt{3} - 1) & \sqrt{3} - 1 \\ \sqrt{3} & -1 \\ 1 & -(\sqrt{3} - 2) \\ -(\sqrt{3} - 2) & 1 \\ 2 & 0 \\ \sqrt{3} & 1 \\ 1 & \sqrt{3} \end{bmatrix} . \quad (6)$$

### 256 D. Maximum Modulation Index

257 The modulation index m can be defined as the ratio of 258 the fundamental component magnitude of the line to neutral 259 inverter output voltage  $V_{1m}$  to the fundamental component 260 magnitude of the six-step mode voltage  $V_{1m6\text{step}} = 2V_{\text{dc}}/\pi$  261 [17]. When the inverter is operating in the linear modulation 262 region, the sum of the applying times of the active voltage 263 vectors is less than the switching period  $T_{\text{s}}$  [18], [19]. The 264 largest value for linear output with the 12-sector and the 265 proposed 24-sector SVPWM techniques,  $m_{\text{max}} = \pi/(2\sqrt{3}) \approx$ 

0.907, coincides with the corresponding value for the three- 266 phase SVPWM [20]. Note that  $m_{\rm max}$  is obtained by solving 267  $t_0=T_{\rm s}-(t_1+t_2+t_3+t_4)=0$  as shown in Appendix B. 268

### IV. HARMONIC CURRENT ANALYSIS 269

The voltage and current waveform quality of the PWM-VSI 270 drives is determined via the switching frequency harmonics, 271 since they determine the switching frequency copper losses 272 and the torque ripple of a motor load and the line current 273 total harmonic distortion of a line-connected VSI. While the 274 copper losses are measured over a fundamental cycle and 275 therefore require a per fundamental cycle (macroscopic) rms 276 ripple current value calculation, the peak and local stresses 277 are properly investigated on a per-carrier cycle (microscopic) 278 basis. Therefore, first a microscopic and then a macroscopic 279 investigation is required [20]. Because, the machine model 280 includes  $(\alpha - \beta)$  and (x - y) components, the harmonic current 281 analysis must be made for the  $(\alpha - \beta)$  and (x - y) currents.

### A. Normalized Harmonic Currents and Fluxes Calculation 283

The stator voltage equations in the stator coordinate system 284 are expressed as follows:

$$v_{s\alpha\beta} = R_{s}i_{s\alpha\beta} + \frac{\mathrm{d}\lambda_{s\alpha\beta}}{\mathrm{d}t}$$

$$v_{sxy} = R_{s}i_{sxy} + L_{lsxy}\frac{\mathrm{d}i_{sxy}}{\mathrm{d}t}$$
(7)

286 where the stator and the rotor flux equations are given by:

$$\lambda_{s\alpha\beta} = L_s i_{s\alpha\beta} + M i_{r\alpha\beta}$$

$$\lambda_{r\alpha\beta} = L_r i_{r\alpha\beta} + M i_{s\alpha\beta}.$$
(8)

The stator flux equation can be rewritten as:

$$\lambda_{\mathbf{s}\alpha\beta} = \sigma L_{\mathbf{s}} i_{\mathbf{s}\alpha\beta} + \frac{M}{L_{\mathbf{r}}} \lambda_{\mathbf{r}\alpha\beta}.$$
 (9)

Substituting (9) in (7), the stator voltage equation can be 289 expressed as follows:

$$v_{s\alpha\beta} = R_{\rm s}i_{s\alpha\beta} + \sigma L_{\rm s}\frac{\mathrm{d}i_{s\alpha\beta}}{\mathrm{d}t} + \frac{M}{L_{\rm r}}\frac{\mathrm{d}\lambda_{\rm r\alpha\beta}}{\mathrm{d}t}.$$
 (10)

If only the harmonic voltages and currents are considered, 291 it will be assumed that the reference voltage vector  $v_{\mathrm{s}\alpha\beta}^*$  is 292 constant over the switching period  $T_{\mathrm{s}}$ , because the switching 293 frequency  $f_{\mathrm{s}}$  is much higher than the fundamental frequency 294  $f_{\mathrm{e}}$ , and that the stator and the rotor time constants are much 295 larger than the switching period, with the resistance drops being 296 neglected [21]. Under these assumptions, the voltages and

currents can be separated in the harmonic components, which 297 change over  $T_{\rm s}$  while the fundamental components remain 298 constant over the same period. Thus, from (7) and (10), the 299 harmonic voltage equations can be expressed as follows:

$$\tilde{v}_{s\alpha\beta} = \sigma L_s \frac{d\tilde{i}_{s\alpha\beta}}{dt}$$

$$\tilde{v}_{sxy} = L_{lsxy} \frac{d\tilde{i}_{sxy}}{dt}$$
(11)

where  $\tilde{v}_{s\alpha\beta}$  is the harmonic voltage and is equal to the 301 difference between the actual voltage vector and the reference 302 vector  $v_{s\alpha\beta}^*$ .

Assuming that the instantaneous harmonic currents are zero 304 at the beginning and at the end of the carrier cycle, the  $(\alpha-\beta)$  305 and (x-y) harmonic stator currents per-carrier cycle can be 306 calculated as follows [20], [22], [23]:

$$\tilde{i}_{s\alpha\beta} = \frac{1}{\sigma L_s} \int_{NT_s}^{(N+1)T_s} (V_{s\alpha\beta k} - v_{s\alpha\beta}^*) dt$$

$$\tilde{i}_{sxy} = \frac{1}{L_{lsxy}} \int_{NT_s}^{(N+1)T_s} (V_{sxyk}) dt.$$
(12)

In (12),  $V_{\mathrm{s}\alpha\beta k}$  and  $V_{\mathrm{s}xyk}$  are the inverter output voltage 308 vectors of the kth state. They change according to the selected 309 switching sequence, since for high  $f_{\mathrm{s}}/f_{\mathrm{e}}$  values, the  $v_{\mathrm{s}\alpha\beta}^*$  term 310 can be assumed as constant within a carrier cycle. Thus, the 311 above integral can be calculated in a closed form.

Because the harmonic current and harmonic flux are only 313 different in scale, and in order to eliminate the need for 314 load parameters in (12), the harmonic flux trajectories can 315 be investigated. Nevertheless, the (x-y) current components 316 are limited by the stator leakage inductance  $L_{\mathrm{ls}xy}$ , which de- 317 pends on the coil pitch of the stator windings [10]. Conse- 318 quently, the harmonic characteristics of the VSI feeding DSIM 319 should be investigated with the introduction of the coefficient 320  $k_{\sigma xy} = \sigma L_{\mathrm{s}}/L_{\mathrm{ls}xy}$ , which is necessary to evaluate and com- 321 pare the performances of the PWM techniques. So, employ- 322 ing (12) and normalizing with respect to  $\lambda_b$ , the per-carrier 323 cycle rms value of the normalized harmonic current can be 324 calculated with:

$$\tilde{I}_{\text{srms}}^{2}(m,\theta) = \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \frac{1}{T_{s}} \int_{NT_{s}}^{(N+1)T_{s}} \left(\tilde{\lambda}_{\text{s}\alpha\beta}^{2} + k_{\sigma xy}^{2} \tilde{\lambda}_{\text{s}xy}^{2}\right) dt$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{\text{s}\alpha\beta\text{rms}}^{2}(m,\theta) + k_{\sigma xy}^{2} \tilde{\lambda}_{\text{s}xy\text{rms}}^{2}(m,\theta)\right)$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{\text{srms}}^{2}(m,\theta)\right) \tag{13}$$

where 
$$\lambda_b=2\sqrt{3}V_{\rm dc}T_{\rm s}/\pi$$
,  $\tilde{\lambda}_{{\rm s}\alpha\beta}=\sigma L_{\rm s}\tilde{i}_{{\rm s}\alpha\beta}$ , and  $\tilde{\lambda}_{{\rm s}xy}=$  326  $L_{{\rm ls}xy}\tilde{i}_{{\rm s}xy}=$  327

TABLE II
SWITCHING FREQUENCY REDUCTION COEFFICIENT

N°	SVPWM Techniques	$k_f$	$f_s$
1	C6 \$ SVPWM12	1	
2	D6 φ SVPWM12-A	2/3	
3	D6 φ SVPWM12-B1	1/2	1
4	D6 φ SVPWM12-B2	5/12	$f_s = \frac{1}{k_f} \cdot f_{sw}$
5	C6 φ SVPWM24	1	v
6	D6 φ SVPWM24-B1	5/6	
7	D6 φ SVPWM24-B2	2/3	

The per-fundamental cycle rms value of the harmonic cur-329 rent determines the waveform quality and harmonic losses. 330 Averaging (13) over a fundamental period results in the global 331 harmonic current calculation as follows:

$$\tilde{I}_{sfrms}^{2}(m) = \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \frac{1}{2\pi} \int_{2\pi} \tilde{\lambda}_{srms}^{2}(m, \theta) d\theta$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{s\alpha\beta frms}^{2}(m) + k_{\sigma xy}^{2} \tilde{\lambda}_{sxy frms}^{2}(m)\right)$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \tilde{\lambda}_{sfrms}^{2}(m). \tag{14}$$

The above integral yields a polynomial function of the mod-333 ulation index m. As an example, the per-fundamental cycle 334 rms normalized harmonic flux  $\tilde{\lambda}_{\rm sfrms}$  was calculated for all 335 the discussed PWM techniques. This results in m dependent 336 analytical formulas summarized in Appendix C.

### 337 B. Performance Comparison

For comparison purposes, the harmonic current analysis is 339 performed at the same average switching frequency  $f_{\rm sw}$  for 340 all the PWM techniques. Therefore, a switching frequency 341 reduction coefficient  $k_{\rm f}$  is introduced for each PWM technique 342 according to Table II. This coefficient can be determined from 343 the ratio of the discontinuous to the continuous PWM tech-344 niques regarding the number of commutations of all legs during 345 one sampling period. The curves of the per-fundamental cycle 346 normalized rms harmonic flux for all the discussed PWM tech-347 niques have been plotted as a function of modulation index m, 348 as shown in Fig. 7. It is clear that the rms value of the harmonic 349 flux varies with the PWM technique used and according to 350 the selected switching sequences. These curves show that the 351 D6  $\phi$  SVPWM12-A has practically the best performance at a 352 low modulation index range, while the D6  $\phi$  SVPWM12-B1-353 (B2) exhibits the best performance in the high modulation index 354 range. However, as the modulation index increases, the C6 355  $\phi$  SVPWM12 performance rapidly degrades compared to the 356 C6  $\phi$  SVPWM24 of the proposed 24-sector PWM scheme, 357 which reveals excellent performance over the whole voltage 358 range. While the D6  $\phi$  SVPWM24-B1-(B2) PWM strategies 359 present harmonic characteristics similar to the ones obtained 360 with the D6  $\phi$  SVPWM12-A-(B1) and (B2) strategies, the

proposed 24-sector PWM techniques allow a sampling fre- 361 quency increase and as a result, the switching frequency can 362 be increased by a factor of two as compared to the 12-sector 363 PWMs. Therefore, significant harmonic current reductions can 364 be achieved as shown in Fig. 7(h) for the worst case, when 365  $k_{\sigma xy} = 10$ .

It should be noted that discontinuous PWM techniques allow 367 a higher sampling rate selection and can be applied in a high 368 voltage range, while continuous ones are advantageous in the 369 low voltage range. In addition, an optimal PWM scheme can be 370 obtained with a transition between these SVPWM strategies to 371 allow rms harmonic current minimization over the whole volt- 372 age range. The intersection points define the optimal transition 373 between different PWM techniques.

Finally, a careful look at D6  $\phi$  SVPWM12-B1 in Fig. 4(c) 375 shows that during one switching period  $T_{\rm s}$ , two inverter legs 376 have commutations twice. D6  $\phi$  SVPWM12-B2 in Fig. 4(d) 377 shows that one inverter leg has commutations twice. This is 378 never the case for D6  $\phi$  SVPWM24-B1 and B2. Therefore, 379 12-sector discontinuous PWMs have a maximum instantaneous 380 switching frequency twice as big as in the case of 24-sector 381 discontinuous PWMs. This fact has an impact on inverter 382 switching losses [14], [20]. While it is not the aim of this paper 383 to evaluate the performance of PWM techniques in terms of 384 inverter switching and conduction losses, it can be expected 385 that the 24-sector discontinuous PWMs will have a better per- 386 formance than the 12-sector ones. Further works on switching 387 and conduction losses are in progress and will be reported in a 388 subsequent paper.

### V. EXPERIMENTAL RESULTS

To confirm the feasibility of the proposed SVPWM tech- 391 niques over the entire voltage range under V/f control, a set 392 of experiments are carried out. The experimental test bench 393 (Fig. 8) is composed of a six-phase VSI feeding a 15 kW 394 DSIM prototype, and the whole control algorithm is tested 395 on a dSPACE DS1104 controller board. The original 320F240 396 firmware does not allow the change in PWM compare registers 397 and action registers many times during a period. So, to allow 398 four changes within PWM period  $T_{\rm s}$ , the flashed firmware is 399 reprogrammed [15], [24]. Hence, it is possible to implement 400 the 12-sector PWM techniques.

On the contrary, for the proposed 24-sector PWM strategies, 402 usually at most two transitions (from low to high or from 403 high to low) occur symmetrically on the corresponding PWM 404 outputs within a sampling period. This allows easier DSP 405 implementation. Then the original 320F240 firmware is used 406 with the help of specially developed user functions that allow 407 the synchronization of six full PWM and three simple PWM 408 simultaneously on the DS1104 DSP board.

These PWM techniques are successfully tested and the 410 following conclusions can be drawn from these experimental 411 results: In the case of the 12-sector PWM strategies, usually 412 more than two transitions (from low to high or from high 413 to low) occur on the corresponding PWM outputs. This in- 414 creases the switching frequency of the inverter legs and compli- 415 cates the experimental test. However, the number of transitions 416

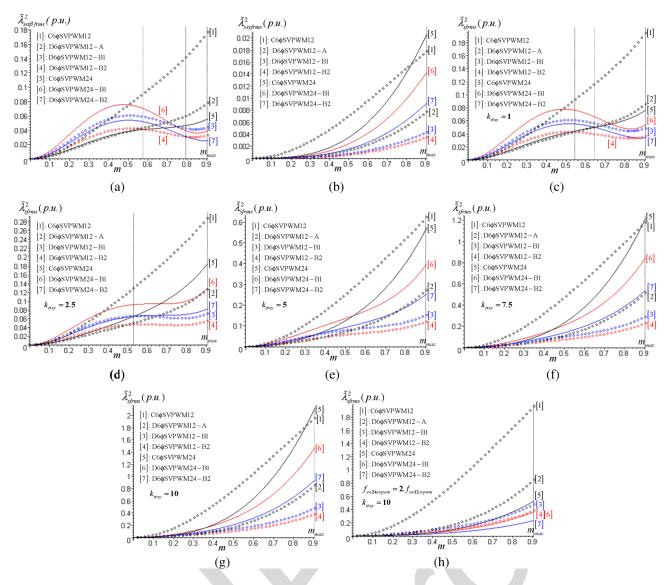

Fig. 7. Per fundamental cycle normalized rms harmonic flux as a function of modulation index m, for all the discussed PWM techniques. (a)  $(\alpha - \beta)$  rms harmonic flux. (b) (x-y) rms harmonic flux. (c), (d), (e), (f), (g) RMS harmonic flux at different leakage coupling  $(k_{\sigma xy} = 1; 2.5; 5; 7.5; 10)$ , at the same average switching frequency  $f_{\rm sw}$ . (h) RMS harmonic flux with  $k_{\sigma xy} = 10$ , at  $f_{\rm s} = 2.f_{\rm sw}$  for the proposed 24-sector PWM techniques.

417 on the corresponding PWM outputs is reduced in the case 418 of the proposed 24-sector PWM strategies, which decrease 419 the switching frequency of the inverter legs and allow easy 420 DSP implementation. In addition, for discontinuous PWM tech-421 niques, at least two PWM outputs remain unchanged during the 422 entire sampling period. Therefore, the carrier frequency can be 423 increased with harmonic losses reduction.

424 Experimental results under constant V/f control, for the 425 cases of C6  $\phi$  SVPWM12, D6  $\phi$  SVPWM12-B2, C6  $\phi$  426 SVPWM24, and D6  $\phi$  SVPWM24-B2 techniques are pre-427 sented in Fig. 9. The average switching frequency is set to 428  $f_{\rm sw}=5$  kHz and the motor is running at 735 r/min with a 429 connected load. As expected, these SVPWM techniques al-430 low the control of the  $(\alpha-\beta)$  and (x-y) current components 431 simultaneously.

432 However, these experimental results demonstrate that the 433 continuous PWM techniques produce a larger amplitude of 434 the harmonic currents in the (x-y) plane as compared to 435 the discontinuous ones where the amplitude of these currents

is minimized. Moreover, the phase current presents a pure 436 sinusoidal shape and the trajectory of the  $(\alpha-\beta)$  stator cur- 437 rent components is a circle for all these PWM techniques, 438 confirming that these currents are controlled as well as (x-y) 439 harmonic currents. Indeed, it should be remembered that the 440 carrier frequency can be increased by a factor of two for a 50% 441 reduction of harmonic losses in the case of C6  $\phi$  SVPWM24, 442 or by a factor three for a 66% reduction in harmonic losses 443 with the D6  $\phi$  SVPWM24-B2 technique. In addition, due 444 to the simplicity and regularity of the proposed 24-sector 445 PWM techniques, low-cost DSPs for motor control may easily 446 be used.

### VI. CONCLUSION 448

In this paper, a new SVPWM technique based on the vector 449 space decomposition suitable for six-phase VSI-fed DSIM has 450 been presented. The switching sequences presented lead to 451 continuous and discontinuous modulation strategies, according 452

466

Experimental results of the SVPWM techniques with the motor operating under a constant V/f control with connected load for  $f_{\rm e}=50$  Hz, at 735 r/min and for the same average switching frequency  $f_{\rm sw}$ . From top to bottom:  $i_{\rm sa1}$  phase current,  $i_{\rm sa}$  current component,  $(\alpha-\beta)$  and (x-y) plane current trajectories. From left to right: C6  $\phi$  SVPWM12, D6  $\phi$  SVPWM12-B2, C6  $\phi$  SVPWM24, and D6  $\phi$  SVPWM24-B2.

453 to the position of zero voltage vectors during each sampling 454 period. It is shown that the harmonic current rms values vary 455 according to the selected switching sequence and the voltage 456 range. Likewise, from this point of view, the continuous PWM 457 technique has an advantage in the low and medium voltage 458 range, while the discontinuous PWM strategy is advantageous 459 in the high voltage range. Thus, the combination of these 460 strategies provides the best harmonic current performance over 461 the whole voltage range. It has been demonstrated that the pro-462 posed 24-sector SVPWM techniques, while easy to implement 463 digitally, allow a switching frequency increase with significant 464 extra stator harmonic currents reduction.

## APPENDIX A VOLTAGE VECTORS APPLYING TIMES CALCULATION

The inverter output voltage vectors are represented in Figs. 3, 467 and Fig. 5 by decimal number k equivalent to the binary number 468 formed by the instantaneous values of the switching functions 469 defined as:

$$k = K_{a1} \times 2^0 + K_{b1} \times 2^1 + K_{c1} \times 2^2 + K_{a2} \times 2^3 + K_{b2} \times 2^4 + K_{c2} \times 2^5.$$
 (A1)

The instantaneous values of the six-phase VSI output voltage 471 vectors  $(v_{a1}, v_{b1}, v_{c1}, v_{a2}, v_{b2}, v_{c2})$  can be determined by using 472 the inverter connection matrix [Mc] as follows: 473

$$[v_{a1} \ v_{b1} \ v_{c1} \ v_{a2} \ v_{b2} \ v_{c2}]^{\mathrm{T}} = [\mathrm{Mc}][K_{a1} \ K_{b1} \ K_{c1} \ K_{a2} \ K_{b2} \ K_{c2}]^{\mathrm{T}}$$
(A2)

where 474

$$[Mc] = \frac{V_{dc}}{3} \begin{bmatrix} 2 & -1 & -1 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ -1 & -1 & 2 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 2 & -1 & -1 \\ 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & -1 & 2 \end{bmatrix}.$$
 (A3)

The inverter output voltage vectors are transformed into 475  $(\alpha-\beta)$ , (x-y), and  $(o_1-o_2)$  planes by means of the transfor- 476 mation matrix  $[Ts]^{-1}$  given in (1), as:

$$\begin{bmatrix} v_{\text{s}\alpha k} \ v_{\text{s}\beta k} \ v_{\text{s}xk} \ v_{\text{s}yk} \ v_{o1k} \ v_{o2k} \end{bmatrix}^{\text{T}} \\ = \left[ \text{Ts} \right]^{-1} \begin{bmatrix} v_{a1} \ v_{b1} \ v_{c1} \ v_{a2} \ v_{b2} \ v_{c2} \end{bmatrix}^{\text{T}}$$
 (A4)

478 For example, when the reference voltage vector is located in 479 sector 1, voltage vectors 41, 9, 11, and 15 are selected and their 480 equivalent binary numbers are defined as:

$$41 = \begin{bmatrix} 1 & 0 & 1 | 0 & 0 & 1 \end{bmatrix}$$

$$9 = \begin{bmatrix} 0 & 0 & 1 | 0 & 0 & 1 \end{bmatrix}$$

$$11 = \begin{bmatrix} 0 & 0 & 1 | 0 & 1 & 1 \end{bmatrix}$$

$$15 = \begin{bmatrix} 0 & 0 & 1 | 1 & 1 & 1 \end{bmatrix}.$$
(A5)

Then the  $(\alpha - \beta)$ , and (x - y) voltages can be calculated by 482 using (A2), and (A4), as follows:

$$\begin{bmatrix} V_{\text{s}\alpha41} & V_{\text{s}\alpha9} & V_{\text{s}\alpha11} & V_{\text{s}\alpha15} \\ V_{\text{s}\beta41} & V_{\text{s}\beta9} & V_{\text{s}\beta11} & V_{\text{s}\beta15} \\ V_{\text{s}x41} & V_{\text{s}x9} & V_{\text{s}x11} & V_{\text{s}x15} \\ V_{\text{s}y41} & V_{\text{s}y9} & V_{\text{s}y11} & V_{\text{s}y15} \end{bmatrix}$$

$$= \frac{V_{\text{dc}}}{2\sqrt{3}} \begin{bmatrix} 2 + \sqrt{3} & 2 + \sqrt{3} & 1 + \sqrt{3} & \sqrt{3} \\ -1 & 1 & 1 + \sqrt{3} & 1 \\ 2 - \sqrt{3} & 2 - \sqrt{3} & 1 - \sqrt{3} & -\sqrt{3} \\ -1 & 1 & 1 - \sqrt{3} & 1 \end{bmatrix}. \quad (A6)$$

The voltage vectors applying times:  $t_1$ ,  $t_2$ ,  $t_3$  and  $t_4$  are

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \begin{bmatrix} V_{s\alpha41} & V_{s\alpha9} & V_{s\alpha11} & V_{s\alpha15} \\ V_{s\beta41} & V_{s\beta9} & V_{s\beta11} & V_{s\beta15} \\ V_{sx41} & V_{sx9} & V_{sx11} & V_{sx15} \\ V_{sy41} & V_{sy9} & V_{sy11} & V_{sy15} \end{bmatrix}^{-1} \begin{bmatrix} v_{s\alpha}^* T_s \\ v_{s\beta}^* T_s \\ v_{sx}^* T_s \\ v_{sy}^* T_s \end{bmatrix}$$

$$t_0 = T_s - (t_1 + t_2 + t_3 + t_4). \tag{A7}$$

Substituting (A6) in (A7), the applying times can be calcu-486 lated as follows:

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} & -1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 & \sqrt{3} + 1 & \sqrt{3} + 1 \\ 0 & 2 & 0 & v - 2 \\ -(\sqrt{3} - 2) & -1 & -(\sqrt{3} + 2) & 1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \\ v_{sx}^* \\ v_{sy}^* \end{bmatrix}.$$
(A8)

With  $v_{sx}^* = v_{sy}^* = 0$ , (A8) can be written as:

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2 V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ 0 & 2 \\ -(\sqrt{3} - 2) & -1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \end{bmatrix} = \begin{bmatrix} T_2 \\ T_5 \\ T_4 \\ -T_1 \end{bmatrix}. \tag{A9}$$

### 488 489

The maximum modulation index  $m_{\rm max}$  can be obtained 491 by solving  $t_0 = T_s - (t_1 + t_2 + t_3 + t_4) = 0$ . For example in 492 sector 1, the sum of the applying times of the active voltage 493 vectors is calculated from (A9) as:

$$\theta \in \left[0, \frac{\pi}{12}\right]$$
  $t_1 + t_2 + t_3 + t_4 = \frac{T_s}{V_{dc}} v_{s\alpha}^*$  (B1)

494 where  $v_{s\alpha}^* = \sqrt{3}V_{1m}\cos(\theta), v_{s\beta}^* = \sqrt{3}V_{1m}\sin(\theta)$ 

$$V_{1m} = mV_{1m6\text{step}} = m2V_{\text{dc}}/\pi.$$

495

$$t_0 = 0: T_s = t_1 + t_2 + t_3 + t_4 = 2\sqrt{3}\frac{T_s}{\pi}m\cos(\theta)$$
 (B2)

From (B2), the modulation index equation can be given as: 496

$$m = \frac{\pi}{2\sqrt{3}\cos(\theta)}.$$
(B3)

To determine the angle  $\theta$  corresponding to  $m_{\rm max}$ , (B3) is 497 derived:

$$\frac{\mathrm{d}m}{\mathrm{d}\theta} = \frac{\pi \sin(\theta)}{2\sqrt{3}\cos^2(\theta)}.$$
 (B4)

Equation (B4) is solved for  $\theta = 0$ . Thus, replacing  $\theta$  in (B3): 499

$$m_{\text{max}} = \frac{\pi}{2\sqrt{3}\cos(0)} = \frac{\pi}{2\sqrt{3}} \approx 0.907.$$
 (B5)

ANALYTICAL FORMULAS OF THE RMS HARMONIC FLUX 501

The per-fundamental cycle rms normalized harmonic flux 502  $\hat{\lambda}_{\rm sfrms}$  was calculated for all the discussed PWM techniques. 503 Only the analytical formulas of the proposed 24-sector PWMs 504 are presented here and the ones of the 12-sector PWMs can be 505 found in [10]. These formulas are given below.

### A. Continuous Modulation C6 φ SVPWM24

$$\tilde{\lambda}_{s\alpha\beta frms}^{2}(m) = \frac{1}{48}m^{2} + \frac{1}{144\pi^{2}} \times (56\sqrt{3} + 63\sqrt{6} - 57\sqrt{2} - 228)m^{3} + \frac{1}{32\pi^{3}}(24\pi + 27 - 21\sqrt{3} - 8\sqrt{3}\pi)m^{4}$$

$$\tilde{\lambda}_{sxyfrms}^{2}(m) = \frac{1}{144\pi^{2}}(63\sqrt{6} + 18 - 52\sqrt{3} - 57\sqrt{2})m^{3}.$$
(C1)

With 
$$v_{sx}^* = v_{sy}^* = 0$$
, (A8) can be written as:   

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2 \, V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ 0 & 2 \\ -(\sqrt{3} - 2) & -1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \end{bmatrix} = \begin{bmatrix} T_2 \\ T_5 \\ T_4 \\ -T_1 \end{bmatrix}.$$
(A9)

# A New PWM Strategy Based on a 24-Sector Vector Space Decomposition for a Six-Phase VSI-Fed Dual Stator Induction Motor

Khoudir Marouani, Lotfi Baghli, Djafar Hadiouche, Abdelaziz Kheloui, and Abderrezak Rezzoug

Abstract—This paper presents a new space vector pulsewidth 6 modulation (SVPWM) technique for the control of six-phase 7 voltage source inverter (VSI)-fed dual stator induction machines 8 (DSIM). A DSIM is an induction machine which has two sets 9 of three-phase stator windings spatially shifted by 30 electrical 10 degrees and fed by two three-phase VSIs. Despite their advantage 11 of power segmentation, these machines are characterized by large 12 zero sequence harmonic currents, and in particular those of order 13  $6k \pm 1$ , which are due to the mutual cancellation between the 14 two stator windings. The proposed SVPWM scheme, while easy 15 to implement digitally, reduces significantly these extra stator 16 harmonic currents. Experimental results, collected from a 15 kW 17 prototype machine controlled by a digital signal processor are 18 presented and discussed.

19 Index Terms—Dual stator induction machines (DSIM), 20 six-phase voltage source inverter (VSI), space vector pulsewidth 21 modulation (SVPWM).

### I. INTRODUCTION

22

TOWADAYS, electrical machine drives are widely used in industrial applications and transportation systems such 25 as electric/hybrid vehicles, traction locomotives and electric 26 propulsion ships, where high-power levels in conjunction with 27 high-performance requirements are more and more demanded. To achieve these high ratings, there are two possible ap-29 proaches; one focuses on the converter side by increasing 30 the number of output voltage levels and the other one on 31 the machine side by increasing the number of phases. In the 32 first approach, the idea is to divide the high dc bus voltage 33 into multiple low levels and therefore to distribute the high 34 power required among cells of reduced-voltage power switches 35 without the problem of dynamic voltage sharing encountered 36 in the series connection of active devices. However, increasing 37 the number of inverter levels adds to the control complexity and 38 may introduce some voltage imbalance problems [1]–[3]. It is a 39 solution well suited for high-power and high-voltage utility ap-

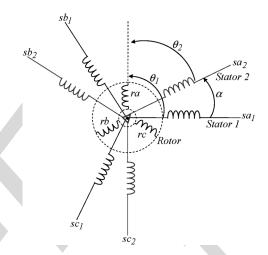

Fig. 1. DSIM windings.

plications. For adjustable speed drives, however, an alternative 40 approach is to use a multiphase machine, i.e., a machine with 41 more than three phases in the stator, since the number of phases 42 is not imposed anyway, given that the machine is connected 43 to the electric supply through a dc/ac converter. The number of 44 phases could be used instead as an additional degree of freedom 45 in the overall system design [4].

Although the answer to the question whether it is better to use 47 a multilevel inverter-fed three-phase machine or a multiphase 48 machine depends on the application, it is undeniable that the 49 latter option offers several advantages which may make it 50 appear very attractive. In fact, the most significant features are 51 a low torque ripple, a reduction in the power per phase and 52 fault-tolerance capability. Other interesting advantages can be 53 pointed out, such as a better torque production per ampere 54 for the same machine volume, higher efficiency and improved 55 reliability [5], [6].

A common type of multiphase machine is the dual stator 57 induction machine (DSIM), where two sets of three-phase 58 windings, spatially phase shifted by 30 electrical degrees, share 59 a common stator magnetic core as shown in Fig. 1.

Due to the development of fast switching power semicon- 61 ductor devices, voltage source inverters (VSIs) are preferred 62 in variable speed machine drives. As VSI-fed multiphase ma- 63 chines are gaining increasing interest for high-power applica- 64 tions, various pulsewidth modulation (PWM) techniques have 65 been developed accordingly, as they strongly affect the overall 66 inverter efficiency and output voltage waveform quality.

In a VSI-fed DSIM, the two stator windings are mutually 69 coupled and small unbalances in the two supply voltages may 70 generate high currents [7]. Furthermore, because of the low 71 impedance seen by the voltage harmonic components generated 72 by the switched voltage waveforms, harmonic currents of high 73 level are circulating uselessly in the two stator windings, adding 74 to the overall losses and therefore to the semiconductor devices 75 ratings [8], [9].

To minimize these extra harmonic currents in a six-phase VSI-fed DSIM, a new 24-sector PWM technique is proposed 8 in this paper and tested on a 15 kW laboratory machine. The 9 digital implementation is carried out on a DS1104 dSPACE 80 controller board. A comparative study between the proposed 81 technique and similar space vector PWM (SVPWM) techniques 82 [5], [10], based on analytical harmonic current analysis, is also 83 developed and discussed.

### II. MACHINE MODEL

The machine model is based on the assumption that space 86 harmonics and magnetic saturation are negligible, and that the 87 two stator three-phase windings are identical and symmetrical 88 with the two neutrals being isolated. In order to derive a practical model suitable for control, a decoupling transformation 90 matrix is used, as proposed in [5]–[7]. The matrix has the 91 following form:

$$[Ts]^{-1} = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} & 0\\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} & \frac{1}{2} & \frac{1}{2} & -1\\ 1 & -\frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & 0\\ 0 & -\frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & \frac{1}{2} & \frac{1}{2} & -1\\ 1 & 1 & 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 1 & 1 \end{bmatrix}.$$

$$(1)$$

By applying (1) to the voltage vector equations, the overall machine model is transformed into three decoupled submodels, written in three independent space coordinates, identified as 95  $(\alpha-\beta)$ , (x-y), and  $(o_1-o_2)$ , respectively.

96 The machine voltage submodel in  $(\alpha - \beta)$  coordinates can be 97 written as:

$$\begin{bmatrix} v_{s\alpha} \\ v_{s\beta} \\ v_{r\alpha} \\ v_{r\beta} \end{bmatrix} = \begin{bmatrix} R_{s} & 0 & 0 & 0 \\ 0 & R_{s} & 0 & 0 \\ 0 & M \dot{\theta} & R_{r} & L_{r} \dot{\theta} \\ -M \dot{\theta} & 0 & -L_{r} \dot{\theta} & R_{r} \end{bmatrix} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ i_{r\alpha} \\ i_{r\beta} \end{bmatrix} + \begin{bmatrix} L_{s} & 0 & M & 0 \\ 0 & L_{s} & 0 & M \\ M & 0 & L_{r} & 0 \\ 0 & M & 0 & L_{r} \end{bmatrix} \frac{d}{dt} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ i_{r\alpha} \\ i_{r\beta} \end{bmatrix}$$
(2)

98 where  $\stackrel{\bullet}{\theta}=\Omega_{\rm m}$  is the rotor mechanical speed, and  $L_{\rm s}=L_{\rm ls}+$  99  $3L_{\rm ms},~L_{\rm r}=L_{\rm lr}+(3/2)L_{\rm mr},~M=(3/\sqrt{2})M_{\rm sr}.~L_{\rm ls}$  and  $L_{\rm lr}$  100 are the stator and rotor leakage inductances in  $(\alpha-\beta)$  coordinates, respectively.

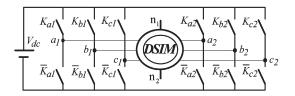

Fig. 2. Six-phase VSI fed DSIM.

The DSIM  $(\alpha - \beta)$  submodel expressed in the stationary 102 reference frame is similar to the three-phase induction machine 103 model [11].

The machine voltage submodel in (x-y) coordinates is 105 given by:

$$\begin{bmatrix} v_{sx} \\ v_{sy} \end{bmatrix} = \begin{bmatrix} R_{s} & 0 \\ 0 & R_{s} \end{bmatrix} \begin{bmatrix} i_{sx} \\ i_{sy} \end{bmatrix} + \begin{bmatrix} L_{lsxy} & 0 \\ 0 & L_{lsxy} \end{bmatrix} \frac{d}{dt} \begin{bmatrix} i_{sx} \\ i_{sy} \end{bmatrix}$$
(3)

where  $L_{{\rm ls}xy}$  is the transformed stator leakage inductance in 107 (x-y) coordinates.

The machine voltage submodel in  $(o_1-o_2)$  coordinates is 109 expressed as follows:

$$\begin{bmatrix} v_{\rm so1} \\ v_{\rm so2} \\ v_{\rm ro} \end{bmatrix} = \begin{bmatrix} R_{\rm s} & 0 & 0 \\ 0 & R_{\rm s} & 0 \\ 0 & 0 & R_{\rm r} \end{bmatrix} \begin{bmatrix} i_{\rm so1} \\ i_{\rm so2} \\ i_{\rm ro} \end{bmatrix} + \begin{bmatrix} L_{\rm lso} & 0 & 0 \\ 0 & L_{\rm lso} & 0 \\ 0 & 0 & L_{\rm lr} \end{bmatrix} \frac{\mathrm{d}}{\mathrm{d}t} \begin{bmatrix} i_{\rm so1} \\ i_{\rm so2} \\ i_{\rm ro} \end{bmatrix}$$

$$(4)$$

where  $L_{\rm lso}$  is the transformed stator leakage inductance in 111  $(o_1-o_2)$  coordinates.

The electromagnetic torque of the DSIM is expressed only 113 in terms of stator and rotor  $(\alpha-\beta)$  current components, since 114 the (x-y) and  $(o_1-o_2)$  counterparts do not contribute to the 115 electromechanical energy conversion, as shown by (3) and (4). 116 The expression of the electromagnetic torque is then as follows: 117

$$T_{\rm e} = pM(i_{\rm s\beta}i_{\rm r\alpha} - i_{\rm s\alpha}i_{\rm r\beta}) \tag{5}$$

118

where p is the number of pole pairs.

The (x-y) and  $(o_1-o_2)$  current components do not con- 120 tribute to the air-gap flux linkages. Hence, they are limited only 121 by the stator resistance and leakage inductance [12], [13]. They 122 produce only losses and therefore must be kept equal to zero or 123 as small as possible.

The transformed voltage equations in the three subframes 125 are well decoupled and, as a result, both machine analysis and 126 control are greatly simplified.

The drive system is a six-phase VSI fed DSIM, as shown 130 in Fig. 2. A combinatorial analysis of the inverter switch 131 states shows 64 switching modes. Thus, 64 different voltage 132 vectors can be applied to the machine. Each voltage vector is 133 represented by a decimal number corresponding to the binary 134 number  $(K_{c2}K_{b2}K_{a2}K_{c1}K_{b1}K_{a1})$ , which gives the state of 135

136 the upper switches. By using the  $(6\times 6)$  transformation matrix 137  $[Ts]^{-1}$ , each voltage vector can be decomposed into  $(\alpha-\beta)$ , 138 (x-y), and  $(o_1-o_2)$  voltages. The  $(o_1-o_2)$  ones are all equal 139 to zero because the neutrals  $(n_1,n_2)$  of the two winding sets 140 are isolated. So the SVPWM strategy operates in two complex 141 planes  $(\alpha-\beta)$  and (x-y). Four variables need to be controlled 142 simultaneously during each sampling period, by generating 143 maximum  $(\alpha-\beta)$  and minimum (x-y) voltage amplitudes. 144 Therefore, during each sampling period, a set of four active 145 voltage vectors must be chosen to fulfil these two conditions, 146 according to the reference voltage vector location. There are 147 numerous ways for choosing such a set.

### 148 A. Six-Phase SVPWM Techniques

The principle of the PWM control techniques proposed in 150 [5] and [10] is to choose switching sequences in such a way 151 that two consecutive nonzero voltage vectors are practically 152 opposite in phase in the (x-y) plane. In this way, each change 153 in the applied vectors leads to a sequence of increases and 154 decreases in (x-y) currents around zero. Moreover, in order 155 to minimize (x-y) harmonic currents and maintain the lowest 156 switching frequency, there are different choices to allocate 157 zero voltage vectors (0, 7, 56 or 63) within the switching 158 sequences. Thus, the switching sequences presented in [10] lead 159 to continuous and discontinuous modulation techniques and, 160 consequently, to different harmonic distortion characteristics. 161 A modulation technique is continuous when on/off switching 162 occurs within every sampling period, for all inverter legs and 163 all sectors. A modulation technique is discontinuous when one 164 (or more) inverter leg stops switching, i.e., the corresponding 165 phase voltage is clamped to the positive or negative dc bus for 166 at least one sector [14].

### 167 B. 12-Sector SVPWM Technique

In the SVPWM technique addressed in [5], only the  $(\alpha-\beta)$  169 voltage vectors having maximum magnitude (45, 41, 9, 11, 170 27, 26, 18, 22, 54, 52, 36, 37) are employed to synthesize 171 the reference voltage vector  $v_{s\alpha\beta}^*$ . These voltage vectors divide 172 the  $(\alpha-\beta)$  plane into 12 sectors and each sector is  $\pi/6$  rad, 173 as shown in Fig. 3. For example, voltage vectors 45, 41, 9, 174 and 11 are selected when the reference voltage vector is located 175 in sector 1. As shown in Fig. 4, continuous and discontinuous 176 modulation techniques can be obtained according to the switch-177 ing sequences given below.

178 1) Continuous Modulation C6  $\phi$  SVPWM12: For example, 179 when the reference voltage vector is located in sector 1, a con-180 tinuous modulation technique (C6  $\phi$  SVPWM12) is obtained 181 with the following sequence:

$$|7-45-41-56-9-11-7|7-11-9-56-41-45-7|$$
.

182 2) Discontinuous Modulation D6  $\phi$  SVPWM12-A: For the 183 same sector 1, a discontinuous modulation technique (D6  $\phi$  184 SVPWM12-A) can be obtained with the following sequence:

$$|7-45-41-9-11-7|7-11-9-41-45-7|$$
.

### 191 C. Proposed 24-Sector SVPWM Technique

As shown in Fig. 4, the switching pattern corresponding 193 to the switching sequences of the 12-sector PWM techniques 194 presents asymmetrical waveforms and usually more than two 195 transitions (from low to high or from high to low) occur on 196 the corresponding PWM outputs within a sampling period, 197 which increases the switching frequency of the inverter legs 198 and causes difficulties for digital signal processor (DSP) im-199 plementation of these strategies. Accordingly, some additional 200 adaptations in DSP programs are necessary to ensure successful 201 experiments [15], [16].

To overcome these drawbacks, the new 24-sector SVPWM 203 technique proposed in this paper combines the maximum

magnitude  $(\alpha - \beta)$  voltage vectors and the ones with half 204 magnitude (1, 57, 8, 15, 3, 59, 24, 31, 2, 58, 16, 23, 6, 205 62, 48, 55, 4, 60, 32, 39, 5, 61, 40, 47) generated by one 206 inverter. These voltage vectors divide the  $(\alpha - \beta)$  plane into 207 twenty four  $\pi/12$ -rad sectors, as shown in Fig. 5. In each 208 sampling period, the reference voltage vector is achieved by 209 selecting a set of three voltage vectors among those having 210 maximum magnitude and a fourth vector among the ones with 211 half magnitude. For example, voltage vectors 41, 9, 11 and 15 212 are selected when the reference voltage vector is located in 213 sector 1. Then, the voltage vectors applying times:  $t_1$ ,  $t_2$ ,  $t_3$  and 214  $t_4$  are obtained as explained in Appendix A. For the remaining 215 time  $t_0 = T_s - (t_1 + t_2 + t_3 + t_4)$ , zero state vectors (0, 7, 56 216 or 63) are applied. Consequently, simple PWM outputs with 217 symmetrical waveforms are obtained. As shown in Fig. 6, 218 only two transitions or less (from low to high or from high 219 to low) occur on the corresponding PWM outputs within a 220 sampling period. This fact decreases the switching frequency 221 of the inverter legs and allows easy DSP implementation. The 222 switching sequences and the corresponding applying times for 223 all sectors are presented in Table I. It should also be noticed 224 that both continuous and discontinuous modulation techniques 225 can be obtained with this new 24-sector SVPWM scheme. This 226 is achieved by selecting the appropriate zero voltage vector 227 locations within the switching sequence.

1) Continuous Modulation C6  $\phi$  SVPWM24: Continuous 229 PWM technique (C6  $\phi$  SVPWM24) can be obtained for all sec-230 tors by selecting the switching sequences presented in Table I. 231 As an example, when the reference voltage vector is located 232 in sector 1, a C6  $\phi$  SVPWM24 is obtained by selecting the 233 following sequence:

$$|56-41-9-11-15-7|7-15-11-9-41-56|$$
.

- 2) Discontinuous Modulation D6  $\phi$  SVPWM24-B1 and B2: 235 Two discontinuous PWM schemes can be obtained through the 236 appropriate positioning of the zero voltage vectors. In sector 1, 237 the examples are as follows.
  - 1) D6  $\phi$  SVPWM24-B1: The first discontinuous modulation 239 technique can be obtained by placing the zero voltage 240 vector both at the beginning and at the end of the switch-241 ing sequence, as follows:

$$|\mathbf{56}-41-9-11-15|15-11-9-41-\mathbf{56}|.$$

2) D6  $\phi$  SVPWM24-B2: The second discontinuous mod- 243 ulation technique is obtained by placing the zero volt- 244 age vector in the middle of the switching sequence, as 245 follows:

$$|41-9-11-15-7|7-15-11-9-41|$$
.

3) Switching Sequences and Applying Time Selection: For 247 optimal DSP implementation and low algorithm execution time, 248 the applying times  $(t_1, t_2, t_3, \text{ and } t_4)$  computation can be 249 simplified by an offline calculation for all sectors in the same 250 manner as for sector 1. As a result, within each sampling period, 251 there is a total of only 12 coefficients  $T_i$  to be calculated in (6). 252

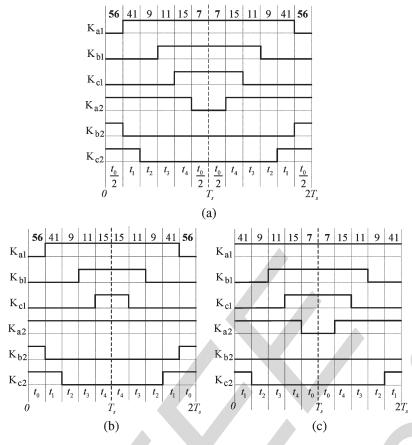

Fig. 6. Twenty-four-sector SVPWM switching sequences when the reference voltage vector is located in sector 1. (a) C6  $\phi$  SVPWM24. (b) D6  $\phi$  SVPWM24-B1. (c) D6  $\phi$  SVPWM24-B2.

253 Table I describes the C6  $\phi$  SVPWM24 switching sequences and 254 applying time selection according to the sector number in the 255  $(\alpha-\beta)$  plane.

$$\begin{bmatrix} T_1 \\ T_2 \\ T_3 \\ T_4 \\ T_5 \\ T_6 \\ T_7 \\ T_8 \\ T_9 \\ T_{10} \\ T_{11} \\ T_{12} \end{bmatrix} = \frac{T_s}{2V_{dc}} \begin{bmatrix} \sqrt{3} - 2 & 1 \\ 1 & -\sqrt{3} \\ 1 & \sqrt{3} - 2 \\ 0 & 2 \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ -(\sqrt{3} - 1) & \sqrt{3} - 1 \\ \sqrt{3} & -1 \\ 1 & -(\sqrt{3} - 2) \\ -(\sqrt{3} - 2) & 1 \\ 2 & 0 \\ \sqrt{3} & 1 \\ 1 & \sqrt{3} \end{bmatrix}. \quad (6)$$

### 256 D. Maximum Modulation Index

257 The modulation index m can be defined as the ratio of 258 the fundamental component magnitude of the line to neutral 259 inverter output voltage  $V_{1m}$  to the fundamental component 260 magnitude of the six-step mode voltage  $V_{1m6\text{step}} = 2V_{\text{dc}}/\pi$  261 [17]. When the inverter is operating in the linear modulation 262 region, the sum of the applying times of the active voltage 263 vectors is less than the switching period  $T_{\text{s}}$  [18], [19]. The 264 largest value for linear output with the 12-sector and the 265 proposed 24-sector SVPWM techniques,  $m_{\text{max}} = \pi/(2\sqrt{3}) \approx$ 

0.907, coincides with the corresponding value for the three- 266 phase SVPWM [20]. Note that  $m_{\rm max}$  is obtained by solving 267  $t_0=T_{\rm s}-(t_1+t_2+t_3+t_4)=0$  as shown in Appendix B. 268

### IV. HARMONIC CURRENT ANALYSIS 269

The voltage and current waveform quality of the PWM-VSI 270 drives is determined via the switching frequency harmonics, 271 since they determine the switching frequency copper losses 272 and the torque ripple of a motor load and the line current 273 total harmonic distortion of a line-connected VSI. While the 274 copper losses are measured over a fundamental cycle and 275 therefore require a per fundamental cycle (macroscopic) rms 276 ripple current value calculation, the peak and local stresses 277 are properly investigated on a per-carrier cycle (microscopic) 278 basis. Therefore, first a microscopic and then a macroscopic 279 investigation is required [20]. Because, the machine model 280 includes  $(\alpha - \beta)$  and (x - y) components, the harmonic current 281 analysis must be made for the  $(\alpha - \beta)$  and (x - y) currents.

### A. Normalized Harmonic Currents and Fluxes Calculation 283

The stator voltage equations in the stator coordinate system 284 are expressed as follows:

$$v_{s\alpha\beta} = R_{s}i_{s\alpha\beta} + \frac{\mathrm{d}\lambda_{s\alpha\beta}}{\mathrm{d}t}$$

$$v_{sxy} = R_{s}i_{sxy} + L_{lsxy}\frac{\mathrm{d}i_{sxy}}{\mathrm{d}t}$$
(7)

286 where the stator and the rotor flux equations are given by:

$$\lambda_{s\alpha\beta} = L_s i_{s\alpha\beta} + M i_{r\alpha\beta}$$

$$\lambda_{r\alpha\beta} = L_r i_{r\alpha\beta} + M i_{s\alpha\beta}.$$
(8)

The stator flux equation can be rewritten as:

$$\lambda_{\mathbf{s}\alpha\beta} = \sigma L_{\mathbf{s}} i_{\mathbf{s}\alpha\beta} + \frac{M}{L_{\mathbf{r}}} \lambda_{\mathbf{r}\alpha\beta}.$$
 (9)

Substituting (9) in (7), the stator voltage equation can be 289 expressed as follows:

$$v_{s\alpha\beta} = R_{\rm s}i_{s\alpha\beta} + \sigma L_{\rm s}\frac{\mathrm{d}i_{s\alpha\beta}}{\mathrm{d}t} + \frac{M}{L_{\rm r}}\frac{\mathrm{d}\lambda_{r\alpha\beta}}{\mathrm{d}t}.$$
 (10)

If only the harmonic voltages and currents are considered, 291 it will be assumed that the reference voltage vector  $v_{\mathrm{s}\alpha\beta}^*$  is 292 constant over the switching period  $T_{\mathrm{s}}$ , because the switching 293 frequency  $f_{\mathrm{s}}$  is much higher than the fundamental frequency 294  $f_{\mathrm{e}}$ , and that the stator and the rotor time constants are much 295 larger than the switching period, with the resistance drops being 296 neglected [21]. Under these assumptions, the voltages and

currents can be separated in the harmonic components, which 297 change over  $T_{\rm s}$  while the fundamental components remain 298 constant over the same period. Thus, from (7) and (10), the 299 harmonic voltage equations can be expressed as follows:

$$\tilde{v}_{s\alpha\beta} = \sigma L_s \frac{d\tilde{i}_{s\alpha\beta}}{dt}$$

$$\tilde{v}_{sxy} = L_{lsxy} \frac{d\tilde{i}_{sxy}}{dt}$$
(11)

where  $\tilde{v}_{s\alpha\beta}$  is the harmonic voltage and is equal to the 301 difference between the actual voltage vector and the reference 302 vector  $v_{s\alpha\beta}^*$ .

Assuming that the instantaneous harmonic currents are zero 304 at the beginning and at the end of the carrier cycle, the  $(\alpha-\beta)$  305 and (x-y) harmonic stator currents per-carrier cycle can be 306 calculated as follows [20], [22], [23]:

$$\tilde{i}_{s\alpha\beta} = \frac{1}{\sigma L_s} \int_{NT_s}^{(N+1)T_s} (V_{s\alpha\beta k} - v_{s\alpha\beta}^*) dt$$

$$\tilde{i}_{sxy} = \frac{1}{L_{lsxy}} \int_{NT_s}^{(N+1)T_s} (V_{sxyk}) dt.$$
(12)

In (12),  $V_{\mathrm{s}\alpha\beta k}$  and  $V_{\mathrm{s}xyk}$  are the inverter output voltage 308 vectors of the kth state. They change according to the selected 309 switching sequence, since for high  $f_{\mathrm{s}}/f_{\mathrm{e}}$  values, the  $v_{\mathrm{s}\alpha\beta}^*$  term 310 can be assumed as constant within a carrier cycle. Thus, the 311 above integral can be calculated in a closed form.

Because the harmonic current and harmonic flux are only 313 different in scale, and in order to eliminate the need for 314 load parameters in (12), the harmonic flux trajectories can 315 be investigated. Nevertheless, the (x-y) current components 316 are limited by the stator leakage inductance  $L_{\mathrm{ls}xy}$ , which de- 317 pends on the coil pitch of the stator windings [10]. Conse- 318 quently, the harmonic characteristics of the VSI feeding DSIM 319 should be investigated with the introduction of the coefficient 320  $k_{\sigma xy} = \sigma L_{\mathrm{s}}/L_{\mathrm{ls}xy}$ , which is necessary to evaluate and com- 321 pare the performances of the PWM techniques. So, employ- 322 ing (12) and normalizing with respect to  $\lambda_b$ , the per-carrier 323 cycle rms value of the normalized harmonic current can be 324 calculated with:

$$\tilde{I}_{\text{srms}}^{2}(m,\theta) = \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \frac{1}{T_{s}} \int_{NT_{s}}^{(N+1)T_{s}} \left(\tilde{\lambda}_{\text{s}\alpha\beta}^{2} + k_{\sigma xy}^{2} \tilde{\lambda}_{\text{s}xy}^{2}\right) dt$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{\text{s}\alpha\beta\text{rms}}^{2}(m,\theta) + k_{\sigma xy}^{2} \tilde{\lambda}_{\text{s}xy\text{rms}}^{2}(m,\theta)\right)$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{\text{srms}}^{2}(m,\theta)\right) \tag{13}$$

where 
$$\lambda_b=2\sqrt{3}V_{\rm dc}T_{\rm s}/\pi$$
,  $\tilde{\lambda}_{{\rm s}\alpha\beta}=\sigma L_{\rm s}\tilde{i}_{{\rm s}\alpha\beta}$ , and  $\tilde{\lambda}_{{\rm s}xy}=$  326  $L_{{\rm ls}xy}\tilde{i}_{{\rm s}xy}=$  327

TABLE II
SWITCHING FREQUENCY REDUCTION COEFFICIENT

N°	SVPWM Techniques	$k_f$	$f_s$
1	C6 \$ SVPWM12	1	
2	D6 φ SVPWM12-A	2/3	
3	D6 φ SVPWM12-B1	1/2	1
4	D6 φ SVPWM12-B2	5/12	$f_s = \frac{1}{k_f} \cdot f_{sw}$
5	C6 φ SVPWM24	1	v

7	D6 φ SVPWM24-B2	2/3	

The per-fundamental cycle rms value of the harmonic cur-329 rent determines the waveform quality and harmonic losses. 330 Averaging (13) over a fundamental period results in the global 331 harmonic current calculation as follows:

$$\tilde{I}_{\text{sfrms}}^{2}(m) = \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \frac{1}{2\pi} \int_{2\pi}^{2\pi} \tilde{\lambda}_{\text{srms}}^{2}(m, \theta) d\theta$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \left(\tilde{\lambda}_{\text{s}\alpha\beta\text{frms}}^{2}(m) + k_{\sigma xy}^{2} \tilde{\lambda}_{\text{s}xy\text{frms}}^{2}(m)\right)$$

$$= \left(\frac{\lambda_{b}}{\sigma L_{s}}\right)^{2} \tilde{\lambda}_{\text{sfrms}}^{2}(m). \tag{14}$$

The above integral yields a polynomial function of the mod-333 ulation index m. As an example, the per-fundamental cycle 334 rms normalized harmonic flux  $\tilde{\lambda}_{\rm sfrms}$  was calculated for all 335 the discussed PWM techniques. This results in m dependent 336 analytical formulas summarized in Appendix C.

### 337 B. Performance Comparison

For comparison purposes, the harmonic current analysis is 339 performed at the same average switching frequency  $f_{\rm sw}$  for 340 all the PWM techniques. Therefore, a switching frequency 341 reduction coefficient  $k_{\rm f}$  is introduced for each PWM technique 342 according to Table II. This coefficient can be determined from 343 the ratio of the discontinuous to the continuous PWM tech-344 niques regarding the number of commutations of all legs during 345 one sampling period. The curves of the per-fundamental cycle 346 normalized rms harmonic flux for all the discussed PWM tech-347 niques have been plotted as a function of modulation index m, 348 as shown in Fig. 7. It is clear that the rms value of the harmonic 349 flux varies with the PWM technique used and according to 350 the selected switching sequences. These curves show that the 351 D6  $\phi$  SVPWM12-A has practically the best performance at a 352 low modulation index range, while the D6  $\phi$  SVPWM12-B1-353 (B2) exhibits the best performance in the high modulation index 354 range. However, as the modulation index increases, the C6 355  $\phi$  SVPWM12 performance rapidly degrades compared to the 356 C6  $\phi$  SVPWM24 of the proposed 24-sector PWM scheme, 357 which reveals excellent performance over the whole voltage 358 range. While the D6  $\phi$  SVPWM24-B1-(B2) PWM strategies 359 present harmonic characteristics similar to the ones obtained 360 with the D6  $\phi$  SVPWM12-A-(B1) and (B2) strategies, the

proposed 24-sector PWM techniques allow a sampling fre- 361 quency increase and as a result, the switching frequency can 362 be increased by a factor of two as compared to the 12-sector 363 PWMs. Therefore, significant harmonic current reductions can 364 be achieved as shown in Fig. 7(h) for the worst case, when 365  $k_{\sigma xy} = 10$ .

It should be noted that discontinuous PWM techniques allow 367 a higher sampling rate selection and can be applied in a high 368 voltage range, while continuous ones are advantageous in the 369 low voltage range. In addition, an optimal PWM scheme can be 370 obtained with a transition between these SVPWM strategies to 371 allow rms harmonic current minimization over the whole volt- 372 age range. The intersection points define the optimal transition 373 between different PWM techniques.

Finally, a careful look at D6  $\phi$  SVPWM12-B1 in Fig. 4(c) 375 shows that during one switching period  $T_{\rm s}$ , two inverter legs 376 have commutations twice. D6  $\phi$  SVPWM12-B2 in Fig. 4(d) 377 shows that one inverter leg has commutations twice. This is 378 never the case for D6  $\phi$  SVPWM24-B1 and B2. Therefore, 379 12-sector discontinuous PWMs have a maximum instantaneous 380 switching frequency twice as big as in the case of 24-sector 381 discontinuous PWMs. This fact has an impact on inverter 382 switching losses [14], [20]. While it is not the aim of this paper 383 to evaluate the performance of PWM techniques in terms of 384 inverter switching and conduction losses, it can be expected 385 that the 24-sector discontinuous PWMs will have a better per- 386 formance than the 12-sector ones. Further works on switching 387 and conduction losses are in progress and will be reported in a 388 subsequent paper.

### V. EXPERIMENTAL RESULTS

To confirm the feasibility of the proposed SVPWM tech- 391 niques over the entire voltage range under V/f control, a set 392 of experiments are carried out. The experimental test bench 393 (Fig. 8) is composed of a six-phase VSI feeding a 15 kW 394 DSIM prototype, and the whole control algorithm is tested 395 on a dSPACE DS1104 controller board. The original 320F240 396 firmware does not allow the change in PWM compare registers 397 and action registers many times during a period. So, to allow 398 four changes within PWM period  $T_{\rm s}$ , the flashed firmware is 399 reprogrammed [15], [24]. Hence, it is possible to implement 400 the 12-sector PWM techniques.

On the contrary, for the proposed 24-sector PWM strategies, 402 usually at most two transitions (from low to high or from 403 high to low) occur symmetrically on the corresponding PWM 404 outputs within a sampling period. This allows easier DSP 405 implementation. Then the original 320F240 firmware is used 406 with the help of specially developed user functions that allow 407 the synchronization of six full PWM and three simple PWM 408 simultaneously on the DS1104 DSP board.

These PWM techniques are successfully tested and the 410 following conclusions can be drawn from these experimental 411 results: In the case of the 12-sector PWM strategies, usually 412 more than two transitions (from low to high or from high 413 to low) occur on the corresponding PWM outputs. This in- 414 creases the switching frequency of the inverter legs and compli- 415 cates the experimental test. However, the number of transitions 416

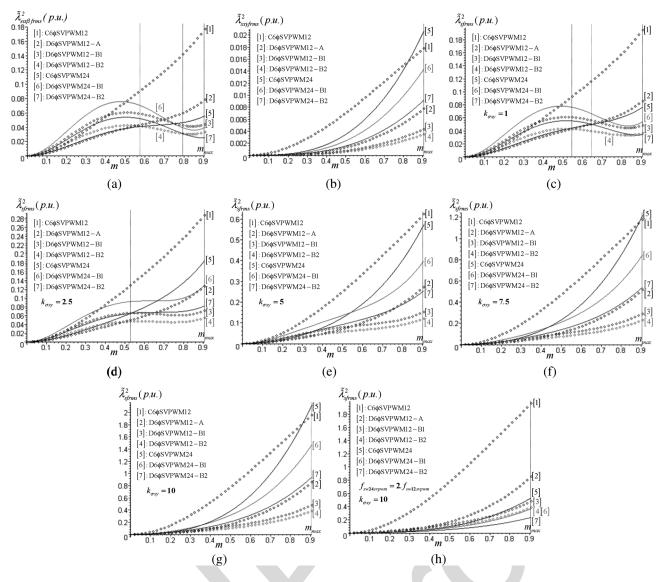

Fig. 7. Per fundamental cycle normalized rms harmonic flux as a function of modulation index m, for all the discussed PWM techniques. (a)  $(\alpha - \beta)$  rms harmonic flux. (b) (x-y) rms harmonic flux. (c), (d), (e), (f), (g) RMS harmonic flux at different leakage coupling  $(k_{\sigma xy} = 1; 2.5; 5; 7.5; 10)$ , at the same average switching frequency  $f_{\rm sw}$ . (h) RMS harmonic flux with  $k_{\sigma xy} = 10$ , at  $f_{\rm s} = 2.f_{\rm sw}$  for the proposed 24-sector PWM techniques.

417 on the corresponding PWM outputs is reduced in the case 418 of the proposed 24-sector PWM strategies, which decrease 419 the switching frequency of the inverter legs and allow easy 420 DSP implementation. In addition, for discontinuous PWM tech-421 niques, at least two PWM outputs remain unchanged during the 422 entire sampling period. Therefore, the carrier frequency can be 423 increased with harmonic losses reduction.

424 Experimental results under constant V/f control, for the 425 cases of C6  $\phi$  SVPWM12, D6  $\phi$  SVPWM12-B2, C6  $\phi$  426 SVPWM24, and D6  $\phi$  SVPWM24-B2 techniques are pre-427 sented in Fig. 9. The average switching frequency is set to 428  $f_{\rm sw}=5$  kHz and the motor is running at 735 r/min with a 429 connected load. As expected, these SVPWM techniques al-430 low the control of the  $(\alpha-\beta)$  and (x-y) current components 431 simultaneously.

432 However, these experimental results demonstrate that the 433 continuous PWM techniques produce a larger amplitude of 434 the harmonic currents in the (x-y) plane as compared to 435 the discontinuous ones where the amplitude of these currents

is minimized. Moreover, the phase current presents a pure 436 sinusoidal shape and the trajectory of the  $(\alpha-\beta)$  stator cur- 437 rent components is a circle for all these PWM techniques, 438 confirming that these currents are controlled as well as (x-y) 439 harmonic currents. Indeed, it should be remembered that the 440 carrier frequency can be increased by a factor of two for a 50% 441 reduction of harmonic losses in the case of C6  $\phi$  SVPWM24, 442 or by a factor three for a 66% reduction in harmonic losses 443 with the D6  $\phi$  SVPWM24-B2 technique. In addition, due 444 to the simplicity and regularity of the proposed 24-sector 445 PWM techniques, low-cost DSPs for motor control may easily 446 be used.

### VI. CONCLUSION

448

In this paper, a new SVPWM technique based on the vector 449 space decomposition suitable for six-phase VSI-fed DSIM has 450 been presented. The switching sequences presented lead to 451 continuous and discontinuous modulation strategies, according 452

466

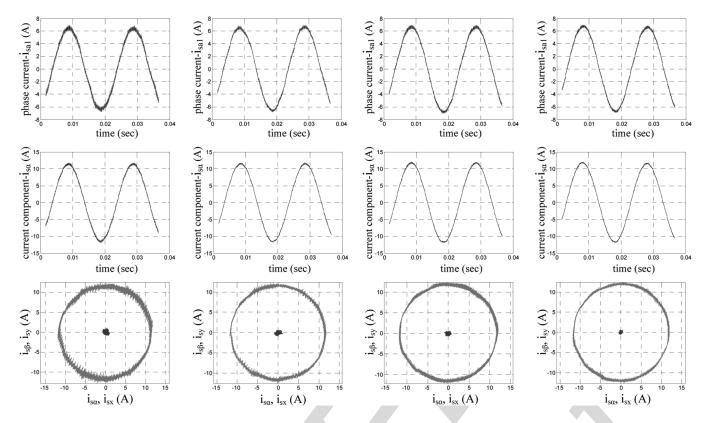

Fig. 8. Experimental test bench.

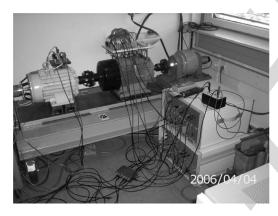

Fig. 9. Experimental results of the SVPWM techniques with the motor operating under a constant V/f control with connected load for  $f_{\rm e}=50$  Hz, at 735 r/min and for the same average switching frequency  $f_{\rm sw}$ . From top to bottom:  $i_{\rm sa1}$  phase current,  $i_{\rm sa}$  current component,  $(\alpha-\beta)$  and (x-y) plane current trajectories. From left to right: C6  $\phi$  SVPWM12, D6  $\phi$  SVPWM12-B2, C6  $\phi$  SVPWM24, and D6  $\phi$  SVPWM24-B2.

453 to the position of zero voltage vectors during each sampling 454 period. It is shown that the harmonic current rms values vary 455 according to the selected switching sequence and the voltage 456 range. Likewise, from this point of view, the continuous PWM 457 technique has an advantage in the low and medium voltage 458 range, while the discontinuous PWM strategy is advantageous 459 in the high voltage range. Thus, the combination of these 460 strategies provides the best harmonic current performance over 461 the whole voltage range. It has been demonstrated that the pro-462 posed 24-sector SVPWM techniques, while easy to implement 463 digitally, allow a switching frequency increase with significant 464 extra stator harmonic currents reduction.

APPENDIX A
VOLTAGE VECTORS APPLYING TIMES CALCULATION

The inverter output voltage vectors are represented in Figs. 3, 467 and Fig. 5 by decimal number k equivalent to the binary number 468 formed by the instantaneous values of the switching functions 469 defined as:

$$k = K_{a1} \times 2^0 + K_{b1} \times 2^1 + K_{c1} \times 2^2 + K_{a2} \times 2^3 + K_{b2} \times 2^4 + K_{c2} \times 2^5.$$
 (A1)

The instantaneous values of the six-phase VSI output voltage 471 vectors  $(v_{a1}, v_{b1}, v_{c1}, v_{a2}, v_{b2}, v_{c2})$  can be determined by using 472 the inverter connection matrix [Mc] as follows: 473

$$[v_{a1} \ v_{b1} \ v_{c1} \ v_{a2} \ v_{b2} \ v_{c2}]^{\mathrm{T}} = [\mathrm{Mc}][K_{a1} \ K_{b1} \ K_{c1} \ K_{a2} \ K_{b2} \ K_{c2}]^{\mathrm{T}}$$
(A2)

where 474

$$[Mc] = \frac{V_{dc}}{3} \begin{bmatrix} 2 & -1 & -1 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ -1 & -1 & 2 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 2 & -1 & -1 \\ 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & -1 & 2 \end{bmatrix}.$$
(A3)

The inverter output voltage vectors are transformed into 475  $(\alpha-\beta)$ , (x-y), and  $(o_1-o_2)$  planes by means of the transfor- 476 mation matrix  $[Ts]^{-1}$  given in (1), as:

$$\begin{bmatrix} v_{\text{s}\alpha k} \ v_{\text{s}\beta k} \ v_{\text{s}xk} \ v_{\text{s}yk} \ v_{o1k} \ v_{o2k} \end{bmatrix}^{\text{T}} \\ = \left[ \text{Ts} \right]^{-1} \begin{bmatrix} v_{a1} \ v_{b1} \ v_{c1} \ v_{a2} \ v_{b2} \ v_{c2} \end{bmatrix}^{\text{T}}$$
 (A4)

478 For example, when the reference voltage vector is located in 479 sector 1, voltage vectors 41, 9, 11, and 15 are selected and their 480 equivalent binary numbers are defined as:

$$41 = \begin{bmatrix} 1 & 0 & 1 | 0 & 0 & 1 \end{bmatrix}$$

$$9 = \begin{bmatrix} 0 & 0 & 1 | 0 & 0 & 1 \end{bmatrix}$$

$$11 = \begin{bmatrix} 0 & 0 & 1 | 0 & 1 & 1 \end{bmatrix}$$

$$15 = \begin{bmatrix} 0 & 0 & 1 | 1 & 1 & 1 \end{bmatrix}.$$
(A5)

Then the  $(\alpha - \beta)$ , and (x - y) voltages can be calculated by 482 using (A2), and (A4), as follows:

$$\begin{bmatrix} V_{\text{s}\alpha41} & V_{\text{s}\alpha9} & V_{\text{s}\alpha11} & V_{\text{s}\alpha15} \\ V_{\text{s}\beta41} & V_{\text{s}\beta9} & V_{\text{s}\beta11} & V_{\text{s}\beta15} \\ V_{\text{s}x41} & V_{\text{s}x9} & V_{\text{s}x11} & V_{\text{s}x15} \\ V_{\text{s}y41} & V_{\text{s}y9} & V_{\text{s}y11} & V_{\text{s}y15} \end{bmatrix}$$

$$= \frac{V_{\text{dc}}}{2\sqrt{3}} \begin{bmatrix} 2 + \sqrt{3} & 2 + \sqrt{3} & 1 + \sqrt{3} & \sqrt{3} \\ -1 & 1 & 1 + \sqrt{3} & 1 \\ 2 - \sqrt{3} & 2 - \sqrt{3} & 1 - \sqrt{3} & -\sqrt{3} \\ -1 & 1 & 1 - \sqrt{3} & 1 \end{bmatrix}. \quad (A6)$$

The voltage vectors applying times:  $t_1$ ,  $t_2$ ,  $t_3$  and  $t_4$  are

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \begin{bmatrix} V_{s\alpha41} & V_{s\alpha9} & V_{s\alpha11} & V_{s\alpha15} \\ V_{s\beta41} & V_{s\beta9} & V_{s\beta11} & V_{s\beta15} \\ V_{sx41} & V_{sx9} & V_{sx11} & V_{sx15} \\ V_{sy41} & V_{sy9} & V_{sy11} & V_{sy15} \end{bmatrix}^{-1} \begin{bmatrix} v_{s\alpha}^* T_s \\ v_{s\beta}^* T_s \\ v_{sx}^* T_s \\ v_{sy}^* T_s \end{bmatrix}$$

$$t_0 = T_s - (t_1 + t_2 + t_3 + t_4). \tag{A7}$$

Substituting (A6) in (A7), the applying times can be calcu-486 lated as follows:

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} & -1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 & \sqrt{3} + 1 & \sqrt{3} + 1 \\ 0 & 2 & 0 & v - 2 \\ -(\sqrt{3} - 2) & -1 & -(\sqrt{3} + 2) & 1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \\ v_{sx}^* \\ v_{sy}^* \end{bmatrix}. \tag{A8}$$

With  $v_{sx}^* = v_{sy}^* = 0$ , (A8) can be written as:

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2 V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ 0 & 2 \\ -(\sqrt{3} - 2) & -1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \end{bmatrix} = \begin{bmatrix} T_2 \\ T_5 \\ T_4 \\ -T_1 \end{bmatrix}. \tag{A9}$$

### 488 489

The maximum modulation index  $m_{\rm max}$  can be obtained 491 by solving  $t_0 = T_s - (t_1 + t_2 + t_3 + t_4) = 0$ . For example in 492 sector 1, the sum of the applying times of the active voltage 493 vectors is calculated from (A9) as:

$$\theta \in \left[0, \frac{\pi}{12}\right]$$
  $t_1 + t_2 + t_3 + t_4 = \frac{T_s}{V_{dc}} v_{s\alpha}^*$  (B1)

494 where  $v_{s\alpha}^* = \sqrt{3}V_{1m}\cos(\theta), v_{s\beta}^* = \sqrt{3}V_{1m}\sin(\theta)$ 

$$V_{1m} = mV_{1m6\text{step}} = m2V_{\text{dc}}/\pi.$$

495

$$t_0 = 0: T_s = t_1 + t_2 + t_3 + t_4 = 2\sqrt{3} \frac{T_s}{\pi} m \cos(\theta)$$
 (B2)

From (B2), the modulation index equation can be given as: 496

$$m = \frac{\pi}{2\sqrt{3}\cos(\theta)}.$$
(B3)

To determine the angle  $\theta$  corresponding to  $m_{\rm max}$ , (B3) is 497 derived:

$$\frac{\mathrm{d}m}{\mathrm{d}\theta} = \frac{\pi \sin(\theta)}{2\sqrt{3}\cos^2(\theta)}.$$
 (B4)

Equation (B4) is solved for  $\theta = 0$ . Thus, replacing  $\theta$  in (B3): 499

$$m_{\text{max}} = \frac{\pi}{2\sqrt{3}\cos(0)} = \frac{\pi}{2\sqrt{3}} \approx 0.907.$$
 (B5)

ANALYTICAL FORMULAS OF THE RMS HARMONIC FLUX 501

The per-fundamental cycle rms normalized harmonic flux 502  $\hat{\lambda}_{\rm sfrms}$  was calculated for all the discussed PWM techniques. 503 Only the analytical formulas of the proposed 24-sector PWMs 504 are presented here and the ones of the 12-sector PWMs can be 505 found in [10]. These formulas are given below.

### A. Continuous Modulation C6 φ SVPWM24

$$\tilde{\lambda}_{s\alpha\beta frms}^{2}(m) = \frac{1}{48}m^{2} + \frac{1}{144\pi^{2}} \times (56\sqrt{3} + 63\sqrt{6} - 57\sqrt{2} - 228)m^{3} + \frac{1}{32\pi^{3}}(24\pi + 27 - 21\sqrt{3} - 8\sqrt{3}\pi)m^{4}$$

$$\tilde{\lambda}_{sxyfrms}^{2}(m) = \frac{1}{144\pi^{2}}(63\sqrt{6} + 18 - 52\sqrt{3} - 57\sqrt{2})m^{3}.$$
(C1)

With 
$$v_{sx}^* = v_{sy}^* = 0$$
, (A8) can be written as:   

$$\begin{bmatrix} t_1 \\ t_2 \\ t_3 \\ t_4 \end{bmatrix} = \frac{T_s}{2 \, V_{dc}} \begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} - 1 & \sqrt{3} - 1 \\ 0 & 2 \\ -(\sqrt{3} - 2) & -1 \end{bmatrix} \begin{bmatrix} v_{s\alpha}^* \\ v_{s\beta}^* \end{bmatrix} = \begin{bmatrix} T_2 \\ T_5 \\ T_4 \\ -T_1 \end{bmatrix}.$$
(A9) 
$$\tilde{\lambda}_{s\alpha\beta frms}^2(m) = \frac{25}{432} m^2 - \frac{25}{5184\pi^2} \times (633\sqrt{2} + 408 - 56\sqrt{3} - 387\sqrt{6}) m^3 \times (633\sqrt{2} + 408 - 56\sqrt{3} - 387\sqrt{6}) m^3 - \frac{25}{576\pi^3} (15\sqrt{3} + 8\sqrt{3}\pi - 24\pi - 45) m^4$$

$$\tilde{\lambda}_{sxy frms}^2(m) = \frac{25}{5184\pi^2} (63\sqrt{6} + 18 - 52\sqrt{3} - 57\sqrt{2}) m^3.$$
MAXIMUM MODULATION INDEX CALCULATION (C2)

### C. Discontinuous Modulation D6 φ SVPWM24-B2

$$\tilde{\lambda}_{\text{s}\alpha\beta\text{frms}}^{2}(m)(m) = \frac{1}{27}m^{2} - \frac{1}{324\pi^{2}} \times (129\sqrt{2} + 45\sqrt{6} + 48 - 56\sqrt{3})m^{3} + \frac{1}{6\pi^{3}}(2\pi + 3 - \sqrt{3})m^{4}$$

$$\tilde{\lambda}_{\text{s}xy\text{frms}}^{2}(m) = \frac{1}{324\pi^{2}}(63\sqrt{6} + 18 - 52\sqrt{3} - 57\sqrt{2})m^{3}.$$
